Overview

Consider maps \( f : \mathbb{C}[[x]]^p \to \mathbb{C}[[x]]^q \) between Cartesian products of formal or convergent power series rings in \( x = (x_1, \ldots, x_n) \). Such an \( f \) is called tactile if it is given by substitution of power series \( a(x) = (a_1(x), \ldots, a_p(x)) \in \mathbb{C}[[x]]^p \) for the variables \( y = (y_1, \ldots, y_p) \) in a power series vector \( g(x, y) \in \mathbb{C}[[x, y]]^q \),

\[ f : a(x) \mapsto g(x, a(x)). \]

Maps of this type – and their associated zerosets \( \{ a \in \mathbb{C}[[x]]^p; g(x, a) = 0 \} \) which will be called *felts* – are ubiquitous in local analytic geometry: arc spaces, local automorphism groups of varieties, \( K \)-equivalence and approximation theorems. They are also the main object of study in chapters 1 to 3 of the present thesis.

Chapter 4 is joint work with D. Wagner and offers a proof for the fact that the set of normal crossings points on a variety (over an algebraically closed field of arbitrary characteristic) is open. We continue with an overview of the chapters:

Chapter 1

In most of the above settings one is interested in finding zeros of tactile maps in spaces of (formal or convergent) power series. This means solving infinitely many equations in infinitely many variables. In the finite dimensional situation, i.e., for analytic maps between affine spaces \( \mathbb{C}^p \) and \( \mathbb{C}^q \), the first instance for solving is given by the Implicit Function Theorem, or its more general companion, the Rank Theorem. Both results are used locally at points where the zeroset is smooth. In the infinite dimensional situation which we encounter with spaces of power series, the corresponding theorems are much more subtle. At their best, they allow to solve tactile equations *from a certain degree on*, meaning that if one knows an approximate power series solution up to sufficiently high degree, then an exact solution exists and its expansion can be determined.

In chapter 1 we utilize and extend in a purely algebraic setting a Rank Theorem for (convergent) tactile maps as it has been established in [HM94]. By local automorphisms of source and target, the tactile map can be linearized in the neighbourhood of a chosen power series. The assumptions of the Theorem involve a *Rank Condition* and an *Order Condition*, which both together are sufficient to yield local linearization. The Rank Condition is also necessary, as it is trivially satisfied by any linear map, and preserved by composition with automorphisms. The Order Condition, formulated in terms of standard bases of ideals, ensures that the higher order terms of \( f \) are suitably dominated by its
linear terms. It turns out that the linearizing local automorphisms lie beyond the class of tactile maps. They are of a more general type, so-called textile maps. These can be characterized by saying that the coefficients of the output series are polynomials in the coefficients of the input series. Actually it turns out that by allowing textile maps as automorphisms, the Rank Theorem can be extended to this more general class of maps between power series spaces (see Theorem 2 below).

Let \( k \) be a field of characteristic 0. A cord is a sequence \( c = (c_\alpha)_{\alpha \in \mathbb{N}^n} \) of constants \( c_\alpha \) in \( k \). The local \( k \)-algebra of formal power series \( k[[x]] = k[[x_1, \ldots, x_n]] \) in \( n \) variables and coefficients in \( k \) naturally identifies with the space \( \mathcal{C} = \mathcal{C}_n(k) \) of cords over \( k \). The maximal ideal of \( k[[x]] \) of power series without constant term is denoted by \( \mathfrak{m} \). We define \( \text{ord} c \) as the order of \( c \) as a power series. The space \( \mathcal{C} \) comes equipped with the \( \mathfrak{m} \)-adic topology induced by the 0-neighborhoods \( \mathcal{C}^N \) of series of order \( \geq k \). Open sets in the \( \mathfrak{m} \)-adic topology will be referred to as \( \mathfrak{m} \)-open, though we will drop the "\( \mathfrak{m} \)" if the topology is clear out of context. In the case \( n = 1 \) we shall speak of arcs and write \( A \) for \( \mathcal{C} \), respectively \( k[[t]] \) for \( k[[x_1]] \).

Elements of \( \mathcal{C} \) are sequences of elements in \( k \) indexed by \( \alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n \). We will consider elements of a Cartesian product \( \mathcal{C}^p, p \in \mathbb{N} \), as sequences in \( k \) which are indexed by \( (\alpha, \alpha_{n+1}) \in \mathbb{N}^n \times \mathbb{N} \) with \( 0 \leq \alpha_{n+1} \leq p - 1 \). A map \( f : \mathcal{C}^m \to \mathcal{C}^p : c \mapsto (f_\alpha(c))_{\alpha \in \mathbb{N}^{n+1}} \) is called textile if for all \( \alpha \) the component \( f_\alpha(c) \) is a polynomial in the coefficients of \( c \). Let \( U \) be a subset of \( \mathcal{C}^m \). A map \( f : U \to \mathcal{C}^p \) is called textile if it is the restriction of a textile map \( \mathcal{C}^m \to \mathcal{C}^p \) to \( U \). Denote by \( k[\mathbb{N}^m_\alpha] \) the polynomial ring \( k[x_j^\alpha ; 1 \leq j \leq m, \alpha \in \mathbb{N}^n] \). The felt defined by a textile map \( f : \mathcal{C}^m \to \mathcal{C}^p \) is the closed subscheme \( \text{Spec} k[\mathbb{N}^m_\alpha]/(f_\alpha ; \alpha \in \mathbb{N}^{n+1}) \) of \( \text{Spec} k[\mathbb{N}^m_\alpha] \). For most applications in section 2 the underlying set of \( k \)-points \( \{ c \in \mathcal{C}^m ; f(c) = 0 \} \) is of primary interest. It is an "algebraic" subset of a countable Cartesian product of copies of \( k \), where the "equations" are infinitely many polynomials in a polynomial ring of countably many variables. Sometimes we will use the term "felt" also for Zariski-open subsets of some felt defined by a textile map.

Any vector of formal power series \( g \in k[[y_1, \ldots, y_m]]^p \) induces a textile map \( f : \mathfrak{m} \cdot \mathcal{C}^m \to \mathcal{C}^p \) via substitution \( f(c) = g(c) \). As we mentioned before, such maps are called tactile. Their zerosets in case \( n = 1 \) are called arc spaces. The tangent map of \( f \) at 0 is given by the linear terms of \( g \).

Textile maps define by restriction morphisms between felts, thus allowing to speak of the category of felts. A felt \( X \) is smooth at a cord \( c \) if there is an \( \mathfrak{m} \)-adic neighbourhood \( U \) of \( c \) in \( \mathcal{C}^m \) such that \( X \cap U \) is isomorphic to an \( \mathfrak{m} \)-open subset of a felt defined by a linear textile map. Tangent spaces and maps can be defined in a natural way.

**Examples.** 1. As a special case of tactiles, let \( X \) be an affine algebraic variety defined in \( k^n \) by polynomials \( f_1, \ldots, f_p \in k[x_1, \ldots, x_m] \). Then

\[
X_{\infty} = \{ a \in A^m, f_1(a) = \ldots = f_p(a) = 0 \}
\]

is the classical arc space associated to \( X \) (see [Nas95]). The point \( a(0) \) lies in \( X \); we say that the arc goes through or is centered at \( a(0) \). The image \( \pi_q(X) \)
of \( X \) in \( (\mathcal{A}/\mathfrak{m}^{q+1})^m \) under the canonical projection is the space of \( q \)-jets which can be lifted to arcs on \( X \), whereas
\[
X_q = \{ a \in (\mathcal{A}/\mathfrak{m}^{q+1})^m : f_1(a) = \ldots = f_p(a) = 0 \text{ mod } \mathfrak{m}^{q+1} \}
\]
is the space of \( q \)-jets on \( X \).

2. Let \( f \in k[x_1, \ldots, x_m] \) and identify \( \mathcal{A} \) with \( k[[t]] \) via \( a = (a_i)_{i \in \mathbb{N}} \mapsto \sum a_it^i \). Consider the felt \( Z \) defined by \( f \). For an integer \( d > 0 \), decompose \( a \in \mathcal{A}^m \) into \( a = \tilde{a} + \hat{a} \), where \( \hat{a} \) denotes the expansion of \( a \) up to degree \( d - 1 \) (its truncation) and \( \tilde{a} \) has order \( \geq d \). We identify \( \hat{a} \) as an element in \( \pi_{d-1}(Z) \) (see example 1) and consider \( f(\tilde{a} + \hat{a}) = 0 \) as an equation in \( \hat{a} \), say \( g(\hat{a}) = 0 \). Of course, \( g \) induces a tactile map \( G : \mathfrak{m}^d, \mathcal{A}^m \to \mathcal{A} \). One of the main aspects of this paper will be to show that for \( d \) sufficiently large, the map \( G \) can be linearized locally (w.r.t. the \( \mathfrak{m} \)-adic topology) in a well defined way (see Theorem 6). Intuitively, this will signify that the recursion equations resulting from \( f(a) = 0 \) for the coefficients of \( a \) will become eventually as good as linear equations. In particular, if \( \tilde{a} \) is an approximate solution for some sufficiently high \( d \), then the existence of the “remainder” \( \hat{a} \) such that \( \tilde{a} + \hat{a} \) is an exact solution is automatically ensured. Geometrically speaking, this says that the fibre over \( \tilde{a} \) under the truncation map \( b \mapsto \hat{b} \) is trivial. For a more general triviality result see Theorem 10.

3. Consider a polynomial recursion of order \( d \) indexed by the naturals:
\[
a_i = f_i(a_{i-1}, \ldots, a_{i-d}), \quad i \geq d,
\]
with \( f_i \in k[y_1, \ldots, y_d] \). It induces a textile map
\[
F : \mathcal{A} \to \mathcal{A} : a \mapsto (a_0, \ldots, a_{d-1}, a_d-f_d(a), a_{d+1}-f_{d+1}(a), \ldots).
\]
Prescribing any initial conditions \( a_0, \ldots, a_{d-1} \) gives rise to a unique solution \( (a_i)_{i \in \mathbb{N}} \) of the recursion. As a variation, let the polynomial recursion be of infinite order having now the form \( a_i = f_i(a_{i-1}, \ldots, a_0) \) with polynomials \( f_i \in k[y_1, \ldots, y_i] \). Again we get a textile map \( F : \mathcal{A} \to \mathcal{A} \), given by \( a \mapsto (a_i - f_i(a))_{i \in \mathbb{N}} \).

For several constructions on the way to linearization it is necessary to have a textile version of the Inverse Mapping Theorem. In contrast to the corresponding theorem in analysis, the result and its proof are mostly algebraic. The basic assumption is that the non-linear terms of the map increase the order of cords stronger than the linear terms do. Write \( f = \ell + h \) with \( \ell \) the (invertible) tangent map of \( f \) at the cord \( c \) in question, and \( h \) the higher order terms. The hypothesis is then that the composition \( \ell h \) (with \( \ell \) linear s.t. \( \ell \ell = \text{id} \)) is contractive, i.e., increases the order of cords (see section 1.1):

The following theorem is a generalization of the inverse function theorem in [HM94] to the setting of textile maps (see Theorem 3 in [1.1].

**Theorem 1** (Inverse Function Theorem). Let \( U \subseteq C^m \) be an \( \mathfrak{m} \)-adic neighbour-}

bouhood of 0 and \( f : U \subseteq C^m \to C^m \) be textile with \( f(0) = 0 \). Assume that \( f = \ell + h \), \( f(U) \subseteq W \) (neighbourhood of 0), where \( \ell : U \to W \) is linear, textile and invertible, i.e., there exists a linear map \( \ell : W \to U \) with \( \ell \circ \ell = \text{id}_W \) and \( \ell \circ \ell = \text{id}_U \). If \( \ell h \) is contractive on \( U \), then \( f \) admits on \( U \) an inverse.
The above result will be further generalized to a parametric version (see 1.3.2) and a version for cords with coefficients in a ring with nilpotent elements (see section 1.1).

**Example.** Consider \( f : m \to m^2 \) given by \( a \to t \cdot a + a^2 \). Here we set \( \ell(a) = t \cdot a \) and \( \tilde{\ell}(a) = t^{-1} \cdot a \). For \( a \in m \), \( \ell h(a) = t^{-1} \cdot a^2 \) is not contractive (the order remains constant for \( a \in m \setminus m^2 \)), whereas it is contractive if we restrict to \( a \in m^2 \). It follows from the theorem that the restriction \( f|_{m^2} : m^2 \to m^3 \) is locally invertible at 0.

In finite dimensional analysis, the Rank Theorem is a trivial consequence of the Inverse Mapping Theorem. In the infinite dimensional context, say Banach spaces or locally convex spaces, and also in the present situation of cord spaces, this is no longer true. In many applications it is the Rank Theorem which is actually needed (despite the numerous important applications of theorems like the Nash-Moser Inverse Function Theorem, [Ham82]) to show the manifold structure of fibres of smooth maps or to prove local triviality.

A first step in this respect is the correct definition of the hypothesis of constant rank. We follow the concept proposed by Hauser and Müller in [HM94] for analytic maps between convergent power series spaces. Working with formal instead of convergent series, the definition slightly simplifies, but is nevertheless somewhat unhandy to grasp. It goes as follows:

Let \( V \) be an \( m \)-adic neighbourhood of 0 in \( C \). A textile map \( \gamma : V \subseteq C \to C^m \) is called a curve (over \( V \)) in \( C^m \). If \( \text{im}(\gamma) \subseteq U \subseteq C^m \) we say that \( \gamma \) defines a curve in \( U \). Let \( f : U \subseteq C^m \to C^p \) be a textile map and let \( J \) be a closed linear direct complement in \( C^p \) of the image \( \text{im}(T_{a_0}f) \) of the tangent map of \( f \) at a cord \( a_0 \). Then \( f \) has constant rank at \( a_0 \) with respect to \( J \) if for all curves \( \gamma \) in \( U \) with \( \gamma(0) = a_0 \) and all curves \( \eta \) in \( C^p \) there exist unique curves \( \rho \) in \( C^m \) and \( \tau \) in \( J \) such that

\[
\eta = T_{a_0}f \cdot \rho + \tau.
\]

If \( f \) is tactile, say induced by a polynomial \( g \in k[y_1, \ldots, y_m] \), then \( T_{a_0}f \cdot \rho \) is given by

\[
\partial_1 g(\gamma) \cdot \rho^1 + \cdots + \partial_m g(\gamma) \cdot \rho^m.
\]

Here, \( \partial_i g \) is the \( i \)th partial derivative of \( g \).

In the applications the occurring textile map \( f \) is often quasi-submersive, i.e., if \( f = \ell + h \) with \( \ell = T_{a_0}f \), then \( \text{im}(h) \subseteq \text{im}(\ell) \). If \( \ell \) is surjective, \( f \) is a submersion.

Let \( \ell : C^m \to C^p \) be textile linear; a textile linear map \( \sigma : C^p \to C^m \) satisfying \( \ell \sigma \ell = \ell \) is called a scission of \( \ell \). Note that a scission provides a left inverse on the image of \( \ell \) and the kernel of \( \ell \sigma \) defines a closed direct complement of this image. In the case of tactile maps we follow [HM94] and construct scissions using the Grauert-Hironaka-Galligo Division Theorem for formal power series (see section 1.2.1). After that we give the construction for arbitrary textile linear maps. This will be achieved by a suitable generalization of the Gauss Algorithm to this context.

Here is one extension of the Rank Theorem in [HM94] which is used in chapter 2.
**Theorem 2** (Rank Theorem). Let \( f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p \) be a textile map on a neighbourhood \( U = \mathbb{C}^m \setminus C^p \) of \( 0 \) with \( f(0) = 0 \). Write \( f \) in the form \( f = \ell + h \) with \( \ell = T_0 f \) the tangent map of \( f \) at 0. Assume that \( \ell \) admits a scission \( \sigma : \mathbb{C}^p \to \mathbb{C}^m \) for which \( \sigma \ell \) is contractive on \( U \), and that \( f \) has constant rank at 0 with respect to \( \ker(\sigma \ell) \). Then there exist locally invertible textile maps \( u : U \to \mathbb{C}^m \) and \( v : f(U) \to \mathbb{C}^p \) at 0 such that
\[
v \circ f \circ u^{-1} = \ell.
\]
This theorem will be extended in sections 1.3.2 and 1.3.3 to the relative case with parameters and a version for cords with coefficients in a ring with nilpotent elements. In this case, if we have the order condition, the form power series or Theorem 2 is easy to see that \( a \) is a smooth cord of \( X_\infty \). In section 2.1.1. we treat the more interesting case when \( u \) is an arc through a point in the singular locus \( \text{Sing}(X) \), but does not lie entirely in it, i.e., \( a(0) \in \text{Sing}(X) \) but \( a \notin \text{Sing}(X)_\infty \).

6. Consider example 2 above in the special case \( f = x + xy \in \mathbb{C}[x,y] \). The induced textile map \( F : \mathbb{C} \cdot \mathcal{A}^2 \to \mathcal{A}, a \mapsto f(a) \) has constant rank at 0 with respect to the complement of \( (t) \cdot \mathcal{A} \). The composition \( \sigma h \) is contractive, where \( h(a^1,a^2) = a^1 a^2 \) and \( \sigma \) is a scission for the linear map \( \ell : (a^1,a^2) \mapsto a^1 \). Thus the Rank Theorem applies and \( F \) can be linearized at 0. The linearizing maps \( u, v \) of the Rank Theorem are given by \( v = \text{id} \) and \( u(a) = (a^1(1 + a^2), a^2) \). Indeed, this \( u \) would be the natural candidate for linearization when viewing \( f \) in the form \( f = x(1 + y) \). Note: It is due to the very simple form of the linear part \( f \) that we can write down \( u \) and \( v \) so explicitly. Taking \( f = tx + xy \in \mathbb{C}[[t]][x,y] \) it is still possible to linearize the induced map on \( \mathbb{C}^2 \), but it is not possible to give closed formulae for \( u, v \). The reason for this lies in the fact that the scission one has to construct is a textile map which is not tactile.

7. In several variables it is in general difficult to prove that a textile map has constant rank. The following example gives a simple textile map which does not have constant rank. By necessity of the rank condition this map is not locally linearizable. Let \( F = x^2 + y^2 \in \mathbb{C}[x,y] \). Set \( \eta := x_1 x_2 + \ldots + (x_1 x_2)^l, l \in \mathbb{N} \), and try to lift the exact solution \((\eta, \eta) \in k[[x_1,x_2]]^2\) of \( F(x,y) = 0 \). Consider the textile map
\[
g : (x_1, x_2)^{l+1} \cdot k[[x_1, x_2]]^2 \to k[[x_1, x_2]] ; g(x,y) = F(\eta + x, \eta + y).
\]
To check whether \( g \) has constant rank we have to lift any relation \((a,b)\) between \( \partial_1 g(0) = \eta \) and \( \partial_2 g(0) = -\eta \) to a relation \((A,B)\) between \( \partial_1 g(\gamma) \) and \( \partial_2 g(\gamma) \) for any \( \gamma = (\gamma_1, \gamma_2) \) that \( \gamma \equiv 0 \mod (s) \) and \( A \equiv a \mod (s) \), \( B \equiv b \mod (s) \). Specify \((a,b) = (1,1)\); a short computation shows that then one has to find \( A', B' \in (s) \subseteq k[[s,x_1,x_2]] \) such that
\[(\eta + \gamma_1)A' - (\eta + \gamma_2)B' = \gamma_2 - \gamma_1.
\]
But this will be impossible (independently of the order of \( \gamma \)) if \( \text{supp}(\gamma_1) \cap \text{supp}(x_1, x_2) = \emptyset \). Therefore \( g \) does not have constant rank at 0. Note that the
situation does not improve by providing an approximative solution of higher
degree, since the above calculation is valid for arbitrary \( l \in \mathbb{N} \). However, consid-
ering \( g \) as a tactile map on \( k[[t]]^2 \), it fulfills the rank condition on some \( m \)-adic
neighbourhood of 0.

**Chapter 2**

This is a collection of six important results in singularity theory being direct
corollaries or special instances of the Rank Theorem. We shall briefly describe
these applications.

(a) Denef and Loeser use the following local triviality result as a main step
to set up motivic integration in the context of singular varieties [DL99] (see
also Lemma 9.1 in [Loo02]). Let \( X \subseteq \mathbb{A}^N_k \) be an affine variety over a field
\( k \) of characteristic 0. Assume \( X \) is given by \( f_1, \ldots, f_p \in k[x_1, \ldots, x_N] \). An
arc (or more precisely a \( k \)-arc) of \( X \) is a \( k[[t]] \)-point of \( X \), i.e., a solution to
\( f_1 = \cdots = f_p = 0 \) in \( k[[t]]^N \). The set of arcs of \( X \) is denoted by \( X_\infty \).
Similarly, an \( m \)-jet is a solution to these equations in \( (k[t]/(t^{m+1}))^N \). Write \( X_m \) for the
set of \( m \)-jets of \( X \). There is a natural projection \( \pi_m : X_\infty \to X_m \). Define
\( Ae = X_\infty \setminus \pi_{e-1}(\text{Sing} X) \) as the space of arcs of \( X \) which do not lie in the
singular locus up to order \( e \). Moreover assume that \( X \) is of pure dimension \( d \).
Denef and Loeser then show that, for sufficiently large \( n \in \mathbb{N} \), the map
\[
\theta_n : \pi_{n+1}(X_\infty) \to \pi_n(X_\infty)
\]
is a piecewise trivial fibration over \( \pi_n(A_e) \) with fibre \( \mathbb{A}^d_k \) [DL99] (2.5). Special-
izing to the case of a hypersurface this means the following: Let \( \gamma \) be an \( n \)-jet of
\( X \) such that not all partial derivatives vanish on \( \gamma \) modulo \( (t)^e+1 \). Then finding
an \( (n+1) \)-jet \( \eta \) of \( X \) with \( \eta = \gamma \mod (t)^{n+1} \) for \( n \geq e \) sufficiently large can be
done by solving a linear system of rank 1. An extension of this result can be
found in [Reg06].
The triviality of the above fibration \( \theta_n \) is one of the key technical results of the
paper [DL99]. Extending the result of Denef and Loeser we show that trivial-
ization can already be obtained on the level of arcs, i.e., the map
\[
X_\infty \to \pi_n(X_\infty)
\]
is a piecewise affine bundle over \( \pi_n(A_e) \) (therefore all the \( \theta_n \) are simultaneously
trivialized). The trivializing map will be textile and can be explicitly described
(see section 2.1).

(b) Grinberg, Kazhdan and Drinfeld show in [GK00] (for \( k = \mathbb{C} \)) and [Dri02]
(for arbitrary \( k \)) a similar factorization result: Let \( X \) be a scheme over \( k \) and
\( \gamma_0 \in X_\infty \setminus (\text{Sing} X)_\infty \). Then the formal neighbourhood \( X_\infty[\gamma_0] \) of \( X_\infty \) in \( \gamma_0 \)
is a product of the form \( Y[y] \times D^\infty \). Here \( Y[y] \) is the formal neighbourhood of a
scheme of finite type over \( k \) in a point \( y \in Y \) and \( D^\infty \) is the product of countably
many formal schemes \( \text{Spf} k[[t]] \). Section 2.2 shows that this local factorization
theorem follows from the Rank Theorem (for \( \text{char } k = 0 \)).

(c) Denef and Lipshitz in [DL84] and Winkel in [Win] study power series solu-
tions in one variable \( x \) with coefficients in \( k \), char \( k = 0 \), of a system of algebraic
differential equations. Here an algebraic differential equation in variables \(x\) and \(y_1, \ldots, y_n\) is a differential equation which is polynomial in \(x, y_1, \ldots, y_n\) and the derivatives of the \(y_i\)'s. Algebraic differential operators in this sense naturally define a textile map \(k[[x]]^n \to k[[x]]^n\). Thus it might prove useful to study the techniques of this paper in the framework of algebraic differential equations. A first instance can be found in section 2.3. There systems of \(n\) explicit differential equations, that is systems of the form \(y^{(q)} = P(x, y, y^{(1)}, \ldots, y^{(q-1)})\), with a vector of polynomials \(P = (P_1, \ldots, P_n)\) and \(q \in \mathbb{N}\), are considered. Solving such a system in \(k[[x]]^n\) for given initial conditions, i.e., the coefficients of the solutions are given up to order \(q - 1\), is equivalent to solving an equation of the form \(f(y) = b\), where \(b \in k[[x]]^n\) and \(\ell\) is a linear textile map.

(d) Tougeron’s Implicit Function Theorem can be seen as a special case of the Rank Theorem. In fact, the proof of the theorem in [Tou68] is based on the following assertion: Let \(\operatorname{rank} F\). In several variables, one can use Tougeron’s Implicit Function Theorem, Thm. I in [Tou68]. Let \(F \in k[[x, y]]\), \(k\) a complete valued field of characteristic 0, and \(F(0) = 0\). Denote by \(\delta = (\delta_1, \ldots, \delta_p)\) the Jacobian of \(F\) w.r.t. \(y = (y_1, \ldots, y_p)\) evaluated at \((x, 0)\), and for \(1 \leq i \leq r \leq p\) set \(y_i' = (y_1, \ldots, y_p)\). Then there are \(Y^i \in k[[x, y]^r; 1 \leq r, 1 \leq j \leq p]^{p}, 1 \leq i \leq r\), such that

\[
F(x, \sum_{i=1}^{r} \delta_i Y^i) = F(x, 0) + \delta \left( \sum_{i=1}^{r} \delta_i y^i \right).
\]

In section 2.4 this will be proven by linearization of the map \((y^1, \ldots, y^r) \mapsto F(x, \sum_{i=1}^{r} \delta_i y_i) - F(x, 0)\) using the Rank Theorem.

(e) Wavrik’s Approximation Theorem, a variation of Artin’s Approximation Theorem, is based on Tougeron’s Implicit Function Theorem, Thm. I_n in [Wav75], and [Art68]. Let \(k\) be a complete valued field of characteristic 0 and let \(F \in k[[x, y]]\) be irreducible, \(x = (x_1, \ldots, x_n)\), \(y = (y_1, \ldots, y_p)\) and \(z = (z_1, \ldots, z_r)\). Wavrik proves that for any integer \(q > 0\) there exists an \(N\) such that if \((\tilde{y}, \tilde{z}) \in k[[x]]^{p+r}\) satisfies \(F(x, \tilde{y}, \tilde{z}) = 0 \mod (x)^N\), then there exist series \((z(x), y(x)) \in k[[x]]^{p+r}\) with

\[
F(x, y(x), z(x)) = 0
\]

and

\[
(y(x), z(x)) = (\tilde{y}, \tilde{z}) \mod (x)^q.
\]

A solution to \(F = 0\) can be obtained as follows: Set \(y_i(x) = \sum_{\alpha \in \mathbb{N}^n} a_{\alpha}^{i} x^\alpha\), \(z_i(x) = \sum_{\alpha \in \mathbb{N}^n} b_{\alpha}^{i} x^\alpha\) and substitute these expressions in \(F(x, y, z)\) for \(y\) respectively \(z\). This gives for each power of \(x\) a polynomial equation in the \(a_{\alpha}^{i}\), \(b_{\alpha}^{i}\). The claim then is that if these equations can be solved up to a sufficiently high degree, then the remaining equations also have a solution. Indeed, it is shown in section 2.4 that solving the remaining equations is equivalent to solving a system of linear equations. In one single variable \(x\), the equivalence follows directly from our Rank Theorem. In several variables, one can use Tougeron’s Implicit Function Theorem.

(f) Lamel and Mir investigate the following question [LM07]: Let \(f: (\mathbb{C}^n, 0) \to \mathbb{C}^n\) be a germ of a holomorphic map of generic rank \(n\), i.e., its Jacobian determinant is a nonzero power series. For germs \(u\) of biholomorphic maps (preserving
the origin) we consider the map defined by \( u \mapsto f \circ u \). In local coordinates this
map is given by substitution of power series, hence is a tactile map. Here naturally
the question for a left inverse to this map arises. Lamel and Mir prove that
it is possible to find one if the derivative \( u'(0) \) is known, see [LM07] Theorem
2.4 and section 2.6 for the precise statement. This result provides information
on the biholomorphic solutions of the equation \( f(u) = b(x) \), where \( b \) is a holomor-
phic germ. The formal version of this result is in fact a special instance of
the Rank Theorem (for the convergent case, apply the same proof to the result
in [HM94]).

It should by now have become clear that the proofs of all the above results are
based on one common principle, linearization: The respective problems are ex-
pressed through certain maps between spaces of power series, and the solution
of the problem corresponds to locally linearizing the map at a given point. This
process is governed by the Rank Theorem.

Chapter 3

This chapter contains various partial results and open questions concerning the
combinatorial, algebraic and geometric structure of jet and arc algebras. These
are – in the case of hypersurfaces – defined as follows. Let \( f \in k[x_1, \ldots, x_m] \) and
denote by \( k[[t]] \) the formal power series ring in one variable \( t \) over the field
\( k \). Substitute \( \sum_{i=0}^{\infty} x_j^i t^i \) for \( x_j \) in \( f \) and expand the result as a power series in
\( t \). It will be of the form

\[
    f \left( \sum_{i=0}^{\infty} x_j^i t^i \right) = F_0 + F_1 t + F_2 t^2 + \ldots,
\]

where \( F_e \in k[x_j^i; 1 \leq i \leq e, 1 \leq j \leq m] \), a polynomial ring in countable many
variables. Especially we have \( F_0 = f(x_0^0, \ldots, x_m^0) \). For \( q \in \mathbb{N} \) the \( q \)th jet scheme
\( X_q \) of \( X = \text{Spec } k[x]/(f) \) is the affine scheme

\[
    X_q = \text{Spec } k[x_j^i; 1 \leq j \leq m, 0 \leq i \leq q]/(F_0, \ldots, F_q).
\]

The coordinate ring of \( X_q \) will be called the \textit{qth jet algebra}. Moreover, the arc
space \( X_\infty \) of \( X \) is the (in general non-Noetherian) scheme defined by the arc
algebra

\[
    k[x_j^i; 1 \leq j \leq m, i \in \mathbb{N}_0]/(F_i; i \in \mathbb{N}_0).
\]

Basic Properties of these algebras are studied in section 3.1. The defining
equations for jet and arc algebras can be computed from the defining equa-
tion \( f \) of the base variety using a specific \( k \)-derivation \( D \) on the polynomial ring
\( k[[x]] = k[x_j^i; 1 \leq j \leq m, i \in \mathbb{N}_0] \). We show that this operator \( D \) has a canonical
form in terms of partial derivatives of \( f \) and the multivariate Bell-Polynomials
(see section 3.2). Denote by \( D^i \) the \( i \)-fold composition of \( D \) with itself, by \( \partial_{0,j} \)
the partial derivative \( \partial / \partial x_0^j \), and write \( D^i|_{k[0,m]} \) for the restriction of \( D^i \) to the
subalgebra \( k[0; m], \)

\[
    k[q;m] = k[x_j^i; 1 \leq j \leq m, 0 \leq i \leq q]
\]
(note that \( k[q;m] \) is graded by the weight \( \text{wt}(x_j^i) = i \)). Then the following holds (cf. Proposition 22 and Corollary 23 in Chapter 3):

**Proposition.** The operator \( D^i|_{[0;m]} = D_{i-1} \ldots D_0 \) has a representation of the form

\[
D^i|_{[0;m]} = \sum_{|\alpha| \leq i} d^i_\alpha \cdot \partial^{\alpha} \partial_0^0
\]

with \( d^i_\alpha \in k[i;m] \), \( \text{wt}(d^i_\alpha) = i \) and \( \partial^{\alpha} \partial_0^0 = \prod_{j=1}^m \partial_{\alpha_j}^{\alpha_j}, \alpha = (\alpha_1, \ldots, \alpha_m) \in \mathbb{N}_0^m \). Moreover, the coefficients \( d^i_\alpha \) fulfill the following recursion:

\[
d^i_\alpha = \sum_{j=1}^m \left( \sum_{e=0}^{i-1} x_{e+1,j} \frac{\partial}{\partial x_j} (d^{i-1}_{\alpha}) + x_j^1 d^{i-1}_{\alpha} \right) E_j \quad (1)
\]

with \( E_j \) the \( j \)th standard basis vector of \( \mathbb{R}^m \).

It turns out that the \( d^i_\alpha \) are natural generalizations of the Bell-polynomials (see [Com74] or [Rio80]) to the multivariate case, Proposition 27 in section 3.2. This gives a natural and combinatorial way to describe the defining ideal of the jet respectively arc space of \( X \) (see Proposition 28):

**Proposition.** Let \( f \in k[x] \) with \( q \)th jet algebra defined by \( F_0, \ldots, F_q \in k[q;m], q \in \mathbb{N} \cup \{\infty\} \). Then for all \( i \)

\[
F_i = \sum_{|\alpha| \leq i} d^i_\alpha \cdot \partial^{\alpha} f(x_0^1, \ldots, x_0^m),
\]

with \( d^i_\alpha \in k[i;m] \), \( \text{wt}(d^i_\alpha) = i \) the multivariate Bell polynomials, and \( \partial^{\alpha} \partial_0^0 = \prod_{j=1}^m \partial_{\alpha_j}^{\alpha_j}, \alpha = (\alpha_1, \ldots, \alpha_m) \in \mathbb{N}_0^m \).

In Question 4.11 of [Mus01] Mustaţă conjectures that the singular locus of the jet scheme of a local complete intersection is precisely the preimage of the singular locus of the base variety under the canonical projection map, i.e.:

Let \( X \) be a l.c.i. variety with \( q \)th jet space \( X_q \) and canonical projection \( \pi_q : X_q \to X \). Is the following assertion true?

\[
(X_q)_{\text{reg}} = \pi_q^{-1}(X_{\text{reg}}).
\]

The canonical morphism \( X_q \to X \) is the morphism induced by the inclusion

\[
k[0;m] \to k[q;m].
\]

In section 3.3 we discuss some examples and approaches towards the problem. We give a prove for a simple special case, namely for hypersurfaces \( X \) with pure dimensional jet schemes.

After this we rise the question for the Hilbert-Poincare (in short HP) series of arc algebras with the grading given by \( \text{wt}(x_j^i) = i \). For smooth base varieties it turns out to be some power of the generating series of the partition function (see section 3.4),
Proposition. Let $X$ be an irreducible hypersurface with arc space given by $k[[x]]/I$, where $I = (F_0,F_1,...)$ is the ideal induced by a defining equation $f \in k[x]$ as before and $I_q = I \cap k[q;m]$. Then with $L = \text{Quot}(k[x_0]/(F_0))$ we get

$$\text{HP}_L \otimes k[x_0]/I_q(t) = \mathbb{H}_q^{m-1},$$

where $\mathbb{H}_q = \text{HP}_{k[1,m]}$.

The chapter closes with the computation of some completions of polynomial rings in countable many variables. The ultimate goal would be to be able to describe the generators for the defining ideal of the completion of the local ring of an arc algebra in a given arc. This would be quite useful for a constructive version of the Grinberg-Kazhdan-Drinfeld formal arc theorem (see section 2.2).

In the Noetherian case of say $k[[x]]/(g_1,...,g_n)$ this can easily be answered using flatness of $k[[x]]$ over $k[[x]]$: $k[[x]](0) = k[[x]]/(g_1,...,g_n) –$ the generators of the ideal in $k[[x]]$ are the same generators as for the ideal in $k[[x]]$, considered as elements of $k[[x]]$. In the non-Noetherian case one loses flatness and thus in general this nice result.

Chapter 4

This is joint work with D. Wagner. It deals with an assertion known to experts in resolution of singularities. Nevertheless, up to the knowledge of the author a reference for the presented situation is lacking.

Let $X$ be an affine subvariety of $\mathbb{A}^n_k$, $k$ algebraically closed (but of arbitrary characteristic). We say that $X$ is algebraic normal crossings (in short anc) at a point $p \in X$ if there are local coordinates $y_1,...,y_n$ at $p$ such that $X$ is locally at $p$ given by $y_1 \cdots y_e = 0$ with $e \leq n$ (in the literature this property is also referred to as simple or strict normal crossings, see [Kol]). By “local coordinates” we mean a regular system of parameters for the local ring $\mathcal{O}_{\mathbb{A}^n,p}$. We say that $X$ is normal crossings (in short nc) at $p$ if $p$ is an algebraic normal crossings point for $\tilde{X}_p$, i.e., if the formal germ of $X$ at $p$ is defined by $y_1 \cdots y_e = 0$, where $y_1,...,y_n$ is a formal coordinate system at $p$. A formal coordinate system is a regular system of parameters for $\mathcal{O}_{\mathbb{A}^n,p}$. The locus of points in which $X$ is algebraic normal crossings (resp. normal crossings) is called the algebraic normal crossings locus of $X$ (resp. normal crossings locus of $X$) and will be denoted by $X_{anc}$ (resp. $X_{nc}$). We prove (see Theorem 18):

Theorem. The normal crossings locus $X_{nc}$ of a hypersurface $X \subseteq \mathbb{A}^n$ is Zariski-open in $X$.

This is done by using the concept of étale neighbourhoods and the Artin Approximation Theorem (see [Art69], Thm. 1.10). All used techniques are applicable to the non-hypersurface case.
Chapter 1

The Rank Theorem for Textile Maps

1.1 Felts and textile maps

In this section we will distinguish subsets of $\mathcal{C}^m$, which are given as the vanishing set of textile maps. For these maps we will provide an inverse mapping theorem and the notion of tangent maps.

1.1.1 Space of Cords and Textile Maps

Let $k$ be a field of characteristic 0. A cord is a sequence $c = (c_\alpha)_{\alpha \in \mathbb{N}^n}$ of constants $c_\alpha$ in $k$. Sometimes we will speak more precisely of an $n$-cord over $k$. The entry $c_\alpha$ is the coefficient of $c$ at index $\alpha$ or $\alpha$-coefficient of $c$. The space $\mathcal{C} = \mathcal{C}_n = \mathcal{C}(k)$ of cords over $k$ naturally identifies with the local $k$-algebra of formal power series $k[[x_1, \ldots, x_n]]$ in $n$ variables and coefficients in $k$. The maximal ideal of $k[[x]]$ of power series without constant term is denoted by $m$. Substitution of the variables by power series in $m$ provides an additional algebraic structure on $\mathcal{C}$. We define $\text{ord } c$ as the order of $c$ as a power series. The space $\mathcal{C}$ comes equipped with the $m$-adic topology induced by the 0-neighborhoods $m^l$ of series of order $\geq l$. Vectors of cords $c = (c_1, \ldots, c_m) \in \mathcal{C}^m$ will be encoded in the following way: For the coefficients $c_{i\alpha}$, $\alpha \in \mathbb{N}^n$, $i = 1, \ldots, m$, we write $c_{(\alpha, i-1)}$ and understand these coefficients as a family indexed by $\mathbb{N}^n + 1$. Thus a vector of $n$-cords $c \in \mathcal{C}^n$ corresponds to an $(n+1)$-cord $(c_{i\beta})_{\beta \in \mathbb{N}^n+1}$ where $c_{ij} = 0$ for $\beta_{n+1} \geq m$ and $c_{ij} = c_{ij}$ for $\beta_{n+1} = i - 1$, $\beta = (\beta_1, \ldots, \beta_n)$.

A textile map $f: \mathcal{C}^m \to \mathcal{C}^p$, $m, p \in \mathbb{N}$, maps cords $c = (c_\alpha)_{\alpha \in \mathbb{N}^{n+1}} \in \mathcal{C}^m$ to cords with coefficients consisting of polynomials in the $c_\alpha$. If the coefficient polynomials are linear, such mappings are called linear. Precisely speaking: $f$ is a textile map if the image of $c \in \mathcal{C}^m$ is of the form

$$f(c) = (f_\alpha(c))_{\alpha \in \mathbb{N}^{n+1}}$$

with $f_\alpha \in k[c_\beta, \beta \in \mathbb{N}^{n+1}]$. The $f_\alpha$ is referred to as the $\alpha$-component of $f$.

Note: Although the definition of textile maps involves infinitely many variables, in many interesting examples they are given by finite data. See the examples.
in the introduction. Let $U$ be a subset of $C^m$. A map $f: U \to C^p$ is called textile if it is the restriction of a textile map $C^m \to C^p$ to $U$. Denote by $k[N^m]$ the polynomial ring $k[x_{ij}; 1 \leq j \leq m, \alpha \in N^n]$. The felt defined by a textile map $f: C^m \to C^p$ is the closed subscheme $\text{Spec} k[N^m]/(f_\alpha; \alpha \in N^{n+1})$ of $\text{Spec} k[N^m]$. For most applications in section 2 the underlying set of $k$-points $\{c \in C^m; f(c) = 0\}$ is of primary interest. It is an “algebraic” subset of a countable Cartesian product of copies of $k$, where the “equations” are infinitely many polynomials in a polynomial ring of countably many variables. Sometimes we will use the term “felt” also for Zariski-open subsets of some felt defined by a textile map.

Let $Y \subseteq C^m$ be a felt. A map $f: Y \to k$ is called regular at $p \in Y$ if there are a Zariski-open neighbourhood $U$ of $p$ and polynomials $g, h \in k[N^m]$ with $h$ non-zero on $U$ such that $f = gh$ on $U$. If $f$ is regular at all points of $Y$ we call it regular (on $Y$). We write $O_Y$ for the $k$-algebra of regular functions on $Y$. A textile map $f: Y \to C^m$ is called regular if its components $f_\alpha$ are regular functions on $Y$, i.e., $f_\alpha \in O_Y$ for all $\alpha \in N^n$.

The sum of textile maps $f, g: Y \to C$ is defined naturally by coefficientwise addition. Moreover we introduce the product of these textile maps by Cauchy-multiplication:

$$f \cdot g := \left( \sum_{\nu + \mu = \alpha} f_\nu g_\mu \right)_\alpha.$$ 

The composition of textile maps $f: C^m \to C^p$ and $g: C^q \to C^m$ is defined as follows: $f_\alpha \in k[x_\beta; \beta \in B_\alpha]$, then

$$(f \circ g)_\alpha(c) := f_\alpha(g_\beta(c)) = f_\alpha(g_\beta(c); \beta \in B_\alpha)$$

for $c \in C$. In each coefficient one has a substitution of polynomials. Call $f$ (right) invertible, if there exists a textile map $g$ such that $f \circ g = \text{id}$.

Any vector of formal power series $g \in k[[y_1, \ldots, y_m]]^p$ induces a textile map $f: m \cdot C^m \to C^p$ via substitution $f(c) = g(c)$. Such maps are called tactile. The felts defined by tactile maps in the case $n = 1$ are called arc spaces. Note that the composition of tactile maps is the same as the tactile map defined by substitution of the corresponding power series.

Sometimes it will be convenient to represent textile linear maps by $N^2$-matrices, i.e., elements in $k^{N^2}$: Let $\ell: A \to A$ be given by $\ell_i(a) = \sum_{j=0}^{\infty} \ell_{ij} a_j$. Then we identify $\ell$ with the $N^2$-matrix $\underline{\ell} = (\ell_{ij})_{i,j \in N}$. In analogy to linear algebra the composition of two textile linear maps $\ell^1, \ell^2$ corresponds to the product of the matrices

$$\ell^1 \cdot \ell^2 = \left( \sum_{l=0}^{\infty} \ell_{il}^1 \ell_{lj}^2 \right)_{i,j}.$$
Note that the last sum is well-defined, since $\ell_{ij} = 0$, $j \in \{1, 2\}$, except for a finite number of $l \in \mathbb{N}$.

Let $L : \mathbb{R}_{>0}^n \to \mathbb{R}_{>0}$ be a positive linear form. Moreover, let $<$ be a monomial ordering on $k[[x_1, \ldots, x_n]]$ induced by $L$, e.g., $x^\alpha < x^\beta$ if $L \cdot \alpha < L \cdot \beta$ or $L \cdot \alpha = L \cdot \beta$ and $\alpha < \beta$ lexicographically. Embed $k[[x_1, \ldots, x_n]]^m$ in $k[[x_1, \ldots, x_{n+1}]]$ by $x^\alpha \cdot e_i \mapsto x^{(\alpha, i-1)}$. For $\beta \in \mathbb{N}^{n+1}$ define $L \cdot \beta$ as $L \cdot \bar{\beta}$. Then we get an ordering on $k[[x_1, \ldots, x_{n+1}]]$ by $x^\alpha < x^\beta$ if: (i) $L \cdot \alpha < L \cdot \beta$ or (ii) $L \cdot \alpha = L \cdot \beta$ and $\alpha < \beta$ lexicographically. This ordering defines a module ordering on $k[[x_1, \ldots, x_n]]^m$ and thus on $\mathcal{C}^m$. Given a module ordering induced by $L$ as above and an element $b \in k[[x]]^m$ the order of $b$ with respect to $L$ is defined as

$$\text{ord}_L b = \min\{L \cdot \alpha ; b_\alpha \neq 0\}.$$ 

Analogously we define the order of a textile map $f : \mathcal{C}^m \to \mathcal{C}^n$ with respect to $L$ as

$$\text{ord}_L f = \min_{\alpha \in \mathbb{N}^{n+1}} \{L \cdot \alpha ; f_\alpha \neq 0\}.$$ 

Usually, if $L$ has been specified, we simply write $\text{ord} b$ respectively $\text{ord} f$. If no linear form has been defined, we will assume $L$ to be $L : (a_1, \ldots, a_n) \mapsto 1 \cdot a_1 + \ldots + 1 \cdot a_n$ (as in the beginning of this section). The ideals of textile maps $f : \mathcal{C}^m \to \mathcal{C}$ of order greater equal $l$, $l \in \mathbb{N}$, define a natural topology on the ring of textile maps $\mathcal{C}^m \to \mathcal{C}$. For obvious reasons we will denote them by $m^l$. It should be clear from context what is meant by $m^l$, an ideal of power series or an ideal of textile maps.

Consider a textile map $h : U \subseteq \mathcal{C}^m \to \mathcal{C}^n$, $U$ an $m$-adic neighbourhood of 0. Without loss of generality one may assume $h(0) = 0$. For $\Gamma \in L(\mathbb{Z}^n)$ the textile map $h$ is called $\Gamma$-shifting on $U$ if

$$\text{ord} (h(a) - h(b)) \geq \text{ord} (a - b) + \Gamma \text{ for all } a, b \in U.$$  

Lemma 1. A textile map $h : U \subseteq \mathcal{C}^m \to \mathcal{C}$ is $\Gamma$-shifting on $U$ if and only if for all $\alpha \in \mathbb{N}^n$ the coefficient $h_\alpha(c)$ is a polynomial in those $c_\nu$ for which $L \cdot \nu \leq L \cdot \alpha - \Gamma$.

For $f \neq 0$ on $U$ the degree of contraction of $f$ on $U$ (with respect to $L$), denoted by $\kappa(f)$, is defined as the maximal $\Gamma$ such that (1.1) is fulfilled. If $f = 0$ on $U$, then we set $\kappa(f) = \infty$. We also say $f$ is contractive of degree $\Gamma$ (on $U$ with respect to $L$). In case $\Gamma > 0$ the map $h$ is simply called contractive. By the Lemma above it is easy to see that the contraction degree is well-defined. Let $f, g$ be textile maps of contraction degree $\Gamma$ resp. $\Theta$ on their domains of definition $U$ respectively $V$. Then $\kappa(f + g) \geq \min\{\Gamma, \Theta\}$ on $U \cap V$. Next assume that the composition $f \circ g$ is well-defined and that $\kappa(f|_{\Theta(V)}) = \Gamma$. Then $\kappa(f \circ g) = \Gamma + \Theta$ on $V$.

It turns out that tactile maps have nice contraction properties. This can be seen in the following example:

Example 1. Consider the “monomial” map $f : U \subseteq \mathcal{C}^m \to \mathcal{C}; c \mapsto c^\alpha$, $\alpha \in \mathbb{N}^n$, with $U = m^{p_1} \times \cdots \times m^{p_m}$. Denote by $p_{\min}$ the minimum of the $p_i$’s. It is immediate that $\kappa(f) = \sum_{i=1}^m \alpha_i p_i - p_{\min}$.
This example shows that one has some control over the degree of contraction of tactiles. By shrinking the domain of definition \( U \) the contraction degree increases!

The notion of contractivity will be used in the following more general context (see section 2.2). Let \( A \) be a local, commutative and unital \( k \)-algebra with nilpotent maximal ideal \( \mathfrak{n} \), i.e., there exists an integer \( N \in \mathbb{N} \) such that \( \mathfrak{n}^N = 0 \). The set of cords with coefficients in \( A \) will be denoted by \( \mathcal{C}_A \). For \( a \in A \) set

\[
\text{pow}(a) = \begin{cases} 
\max\{i; a \in \mathfrak{n}^i\} & a \neq 0 \\
N & a = 0 
\end{cases}
\]

where \( \mathfrak{n}^0 = A \). For an element \( c \in \mathcal{C}_A^m \) we define the refined order of \( a \) as the pair

\[
\text{ord}(c) = (\text{ord}(c), \text{pow}(c_{\text{ord}(c)})) \in \mathbb{N}^2,
\]

where \( \mathbb{N}^2 \) is considered with the lexicographic ordering. If \( (c_i)_i \in \mathbb{N} \) is a family of cords in \( \mathcal{C}_A^m \) with increasing sequence of modified orders \( (\text{ord}(c_i))_i \), then the family is summable. A map \( h: U \subseteq \mathcal{C}_A^m \to \mathcal{C}_A^p \), \( U \) an \( m \)-adic neighbourhood of 0, is called contractive if for all cords \( a \) and \( b \) in \( U \)

\[
\text{ord}(h(a) - h(b)) > \text{ord}(a - b)
\]

holds. If \( A = k \) the only nilpotent ideal in \( A \) is the zero-ideal and both notions of contractivity coincide.

Remark. For other applications it might be reasonable to interchange the order of \( \text{ord} \) and \( \text{pow} \) in the definition of the modified order.

**Theorem 3** (Inverse Mapping Theorem). Let \( U \subseteq \mathcal{C}_A^m \) be an \( m \)-adic neighbourhood of 0 and \( f: U \subseteq \mathcal{C}_A^m \to \mathcal{C}_A^p \) be textile with \( f(0) = 0 \). Assume that \( f = \ell + h \), \( f(U) \subseteq W \) (neighbourhood of 0), where \( \ell: U \to W \) is textile, linear and invertible, i.e., there exists a linear map \( \ell: W \to U \) with \( \ell \circ \ell = \text{id}_W \) and \( \ell \circ \ell = \text{id}_U \). If \( \ell \) is contractive on \( U \), then \( f \) admits on \( U \) an inverse, i.e., there is a textile map \( g: f(U) \to U \) with \( f \circ g = \text{id}_{f(U)} \) and \( g \circ f = \text{id}_U \).

**Proof.** First simplify to the case \( f = \text{id} + h \) with \( h \) contractive on \( U \) by considering \( \ell h = \text{id} + \ell h \). Then recursively define a sequence \( (g_j)_j \in \mathbb{N} \) of textile maps \( U \to \mathcal{C}_A^m \) by \( g_0 = 0 \) and \( g_{j+1} = \text{id} - h \circ g_j \) for \( j \geq 1 \). The sequence \( (g_j)_j \) converges pointwise on \( U \). Indeed, \( g_{j+1} \) can be written as

\[
g_{j+1} = g_0 + \sum_{i=1}^{j+1} D_i,
\]

with \( D_j = g_j - g_{j-1} \). For any \( a \in U \) the family \( (D_j(a))_j \in \mathbb{N} \) is summable: For \( j \geq 2 \) we can write \( D_j \) as

\[
D_j = h \circ g_{j-2} - h \circ g_{j-1},
\]

and thus by contractivity of \( h \)

\[
\text{ord } D_j(a) > \text{ord } D_{j-1}(a)
\]
for any \( a \in U \). Therefore, \( g = \lim g_j \) is a well-defined textile map \( U \rightarrow C_A^\mathbb{N} \). It remains to show that \( g \) is a (right-)inverse for \( f \). But for any \( j \in \mathbb{N} \)

\[
f \circ g - \text{id} = (g - g_j) + (h \circ g - h \circ g_j) + (h \circ g_j - h \circ g_{j-1}),
\]

and each of the three summands on the right hand side tends to 0 for \( j \rightarrow \infty \). Therefore, \( g \) is a right-inverse for \( f \).

It’s not hard to see that \( g \) is in fact also a left-inverse for \( f \). It suffices to show that

\[
(\text{ord}(g_m(f(a)) - a))_{m \in \mathbb{N}}
\]

is an increasing sequence (for all \( a \in U \)) which follows immediately from contractiveness of \( h \).

Remarks. (a) Note that there are textile invertible maps which are not of the special form demanded in the theorem. An example would be

\[
f : A \rightarrow A; (a_i)_i \mapsto (a_0 + a_1^2, a_1, a_2 + a_3^2, a_3, + \ldots).
\]

Nevertheless this textile map may be transformed into a form which allows the use of Theorem 3.

(b) Theorem 3 implies as a special case the classical Inverse Mapping Theorem for formal power series: Let \( f = (f_1, \ldots, f_n) \in k[[x_1, \ldots, x_n]]^n \) with \( f(0) = 0 \). Denote by \( \partial f \) its Jacobian matrix \( (\partial f_i/\partial x_j)_{ij} \). If \( \det \partial f(0) \neq 0 \) then there exist \( g_1, \ldots, g_n \in m \cdot k[[x_1, \ldots, x_n]] \) with

\[
f(g_1(x), \ldots, g_n(x)) = (x_1, \ldots, x_n).
\]

**Lemma 2.** Assume that \( h : U \subseteq C_A^\mathbb{N} \rightarrow A \), \( U \) an \( m \)-adic neighbourhood of 0, is textile with \( h(0) = 0 \). Moreover, let its \( \alpha \)-coefficient \( h_\alpha \) be of the form

\[
h_\alpha = h_\alpha^e + h_\alpha^m \quad \text{with} \quad h_\alpha^e \in A[x_1^e; 1 \leq j \leq m, 0 \leq l < e] \quad \text{and} \quad h_\alpha^m \in n[x_1^e; 1 \leq j \leq m,],
\]

where \( e = |\alpha| \). Then \( h \) is contractive.

**Proof.** For simplicity of notation we restrict to the case \( h : A_A^m \rightarrow A_A \). Let \( a, b \in U \) with \( \text{ord}(a - b) = i \). Write \( a = b + \zeta \) for some \( \zeta \in U \), \( \zeta_i \neq 0 \). By assumption on \( h \) we have \( h_j(a) - h_j(b) = 0 \) for \( 0 \leq j \leq i - 1 \). Using Taylor expansion we see for the \( i \)-th coefficient

\[
h_i(b + \zeta) - h_i(b) = \partial h_i^e(b) \cdot \zeta_i + \partial^2 h_i^m(b) \cdot \zeta_i^2 + \ldots
\]

where \( \partial^l h_i^e(b) \cdot \zeta_i^l \) abbreviates all order \( l \) terms in the Taylor expansion. By assumption on \( h \) all partial derivatives in (1.2) lie in \( n \), thus

\[
pow(h_i(a) - h_i(b)) \geq pow(\zeta_i) + 1 > pow((a - b)_i),
\]

so \( h \) is contractive. \( \square \)

Denote by \( \mathcal{C}(q) \) the set of \( q \)-cords, that is

\[
\mathcal{C}(q) = \{(c_\alpha)_{\alpha \in \mathbb{N}^n} \in k^{n(q+1)} ; |\alpha| < q + 1 \} \cong \mathcal{C} \mod m^{q+1}.
\]

Analogously we introduce \( \mathcal{C}_m(q) \), and especially if \( X \) is the felt defined by a textile map \( f : C^m \rightarrow \mathcal{C} \) the set of \( q \)-cords of \( X \)

\[
X(q) = \{(c_\alpha)_{\alpha \in \mathbb{N}^{n+1}} \in (k^{n(q+1)})^n ; |\alpha| < q + 1, f(c) = 0 \mod m^{q+1} \}.
\]
Clearly, \( X(q) \) has a natural structure as a subscheme of \( \mathbb{A}^{(q+1)m} \). The canonical projections \( X \to X(q) \), resp. \( X(q) \to X(p) \) for \( q \geq p \), induced by truncation of cords, resp. \( q \)-cords, will be denoted by \( \pi_q \), resp. \( \pi^q_p \). We will identify \( C(q) \) with those cords \( c \in C \) such that \( c_\alpha = 0 \) for all \( \alpha \in \mathbb{N}^n \) with \( |\alpha| > q \). Then a textile map \( f : C^m \to C^r \) induces a map \( f_q : C(q)^m \to C(q)^r \) with components \( (f_q)_\alpha \). It’s easy to see that if \( f \) is 0-shifting, then \( f \) is compatible with the truncation maps \( \pi_q \) in the sense that the following diagram is commutative:

\[
\begin{array}{ccc}
C^m & \xrightarrow{f} & C^r \\
\downarrow{\pi_q} & & \downarrow{\pi_q} \\
C^m(q) & \xrightarrow{f_q} & C^r(q) \\
\downarrow{\pi^q_p} & & \downarrow{\pi^q_p} \\
C^m(p) & \xrightarrow{f_p} & C^r(p)
\end{array}
\]

Let \( f : C^m \to C^n \) be a textile map. The felt \( X = f^{-1}(0) \) is called \textit{smooth at a cord} \( c \in X \) if there is an \( m \)-open neighbourhood \( U \) of \( c \) such that \( X \cap U \) is isomorphic to the kernel of a linear textile map. Smoothness of a \((k-)\)point in classical algebraic geometry can be embedded into the theory of felts in the following way: Let \( X \) be a subvariety of \( \mathbb{A}^n_k \) given by the ideal \( (f_1, \ldots, f_p) \subseteq k[x_1, \ldots, x_n] \). Consider the tactile map

\[
F_X : \mathbb{A}^n \to \mathbb{A}^p ; a \mapsto (f_1(a), \ldots, f_p(a)).
\]

The \( k \)-points of \( X \), i.e., elements \( b = (b^1, \ldots, b^n) \in k^n \) with \( f_i(b) = 0 \) for all \( i \), correspond to arcs \( a = (a^1, \ldots, a^n) \in X_\infty \) with \( a^i = (b^i, 0, \ldots) \). Using the classical Implicit Function Theorem or the Rank Theorem from section 1.3 it is obvious that \( X_\infty \) is smooth at \( a \) if \( b \) is a smooth point of \( X \). With the same methods one shows that all arcs \( a \in X_\infty \) with \( a(0) \) a smooth point of \( X \) are smooth cords of \( X_\infty \).

### 1.1.2 Differential Calculus

This section provides the basic definitions for the differential apparatus in the context of textile maps. Consider a textile map \( f : C^m \to C ; c \mapsto (f_\alpha(c))_\alpha \). For \( \nu \in \mathbb{N}^{n+1} \) the \textit{partial derivative of} \( f \) \textit{with respect to} \( \nu \) is defined by coefficientwise differentiation:

\[
\partial_\nu f(c) := \left( \frac{\partial f_\alpha(c)}{\partial \nu} \right)_{\alpha \in \mathbb{N}^n}.
\]

Obviously \( \partial_\nu \) is a \( k \)-derivation on \( C \). We write \( \partial f(a) \) for the vector

\[
(\partial_\nu f(a))_{\nu \in \mathbb{N}^{n+1}}.
\]

The \textit{directional derivative of} \( f \) \textit{in} \( a \in C^m \) \textit{in direction of} \( v \in C^m \), is given by

\[
T_a f \cdot v := \frac{1}{s} \left( f(a + sv) - f(a) \right)_{s=0}.
\]

Using the notation \( (\partial f)(a) \bullet v := \sum_{\nu \in \mathbb{N}^{n+1}} \partial_\nu f(a) v_\nu \) this yields for a textile map \( f \):

\[
T_a f \cdot v = (\partial f)(a) \bullet v.
\]
1.2. SCISSIONS OF LINEAR MAPS

In the case of tactile maps the directional derivative can be calculated as usually. Let \( F : \mathbb{C}^m \to \mathbb{C} \) be given by \( c \mapsto f(c) \), with \( f \in k[x_1, \ldots, x_m] \), then
\[
T_a F \cdot v = \partial_1 f(a) \cdot v_1 + \cdots + \partial_m f(a) \cdot v_m.
\]

It’s easy to see that each \( f \) has a Taylor expansion around \( a \) given by
\[
f(y) = \sum_{\nu \in \mathbb{N}^{n+1}} \frac{1}{\nu!} (\partial^\nu f)(a) (y-a)^\nu.
\]

Consider textile maps \( f : \mathbb{C}^m \to \mathbb{C}^p \) and \( g : \mathbb{C}^l \to \mathbb{C}^m \) with well-defined composition \( f \circ g \). The chain-rule for partial derivatives is given by:
\[
\partial^\nu (f \circ g)(a) = \partial_f(g(a)) \cdot \partial^\nu g(a).
\]

More generally one deduces the following properties of the derivative:

**Proposition 3.** With the above assumptions the following holds:
1. \( \partial(f \circ g)(a) = (\partial f(g(a)) \cdot \partial g(a))_\nu \)
2. Let \( \phi \) be a textile linear map, then
\[
T_a (\phi \circ f) \cdot v = \phi(T_a f \cdot v).
\]
3. Let \( \phi \) be of the form \( \phi = \text{id} + g \), and \( f \circ g \) well-defined, then
\[
T_a (f \circ \phi) \cdot v = \partial f(\phi(a)) \cdot v + \partial f(\phi(a)) \cdot (\partial g(a) \cdot v)
= T_{\phi(a)} f \cdot v + T_{\phi(a)} f \cdot (T_a g(a) \cdot v)
\]

**Proof.** For the easy calculations see [Bru05]. \( \square \)

1.2 Scissions of linear maps

We recall the notion of scissions of linear maps (cf. [HM94], p. 99). In Theorem 3 the inverse of a map is constructed using the inverse of its tangent map. For the proof of the Rank Theorem (see section 1.3) a similar construction is needed.

There the linearizing automorphisms rely on inverting the tangent map on its image (and going back to a direct complement of its kernel).

Let \( \ell : V \to W \) be a linear map of \( k \)-vector spaces \( V \) and \( W \). A scission of \( \ell \) is a linear map \( \sigma : W \to V \) with \( \ell \sigma \ell = \ell \). Scissions provide projections \( \pi_{\ker} := \text{id} - \sigma \ell \) onto \( \ker(\ell) \) and \( \pi_{\im} := \ell \sigma \) onto \( \im(\ell) \). Thus, \( \sigma \) induces direct sum decompositions
\[
V = \ker(\ell) \oplus \im(\sigma \ell) \quad \text{and} \quad W = \im(\ell) \oplus \ker(\ell \sigma).
\]

On the other hand each direct sum decomposition of the form
\[
V = \ker(\ell) \oplus L, \quad W = \im(\ell) \oplus J
\]
induces a scission \( \sigma \) of \( \ell \) by
\[
\sigma := (\ell|_L)^{-1} \circ \pi,
\]
where \( \pi \) is the projection from \( W \) onto \( \text{im}(\ell) \) with kernel \( J \). In the following sections we will explicitly construct scissions for textile linear maps. This is necessary to obtain precise information on the degree of contraction of the scission used to linearize a map of constant rank. For the case of \( k[[x]] \)-linear maps \( \ell \), the degree of contraction will be given by the maximal order of a standard basis of the module \( \text{im}(\ell) \).

### 1.2.1 Scissions of \( k[[x]] \)-linear maps

We start with a short reminder on standard bases. Most of the notation has already been introduced in section \[1.1.1\] Write \( x^{\alpha,j} \), \( \alpha \in \mathbb{N}^n \), \( j \in \{1, \ldots, m\} \), for the vector \( (0, \ldots, x^\alpha, 0, \ldots, 0)^T \) in \( k[[x]]^m \), where \( x^\alpha \) is at the \( j \)th component. For \( \alpha \in \mathbb{N}^n \) we use the usual multindex notation, i.e., \( x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n} \). Thus, each element \( a \in k[[x]]^m \) can be uniquely written as

\[
a = \sum_{\alpha,j} a_{\alpha,j} x^{\alpha,j}.
\]

Fix a monomial order \( < \) on \( \mathbb{N}^n \). We assume that it is induced by a positive linear form \( L \) on \( \mathbb{R}_{\geq 0}^n \). Extend this order to a module ordering on \( k[[x]]^m \), again denoted by “\(<\)”. The support of an element \( a \in k[[x]]^m \) is defined as

\[
\text{supp}(a) := \{(\alpha,j) \in \mathbb{N}^{n+1}; a_{\alpha,j} \neq 0\}.
\]

By \( \text{in}(a) \) we denote the initial monomial vector \( x^{\alpha,j} \) of \( a \), i.e.,

\[
(\alpha,j) = \min_{<} \text{supp}(a).
\]

An element \( a \in k[[x]]^m \) is called \( L \)-monic or just monic, if the coefficient of \( \text{in}(a) \) is 1. Let \( M \) be a submodule of \( k[[x]]^p \). Then \( \text{in}(M) \) denotes the initial module of \( M \): \( \text{in}(M) := \{\text{in}(a) ; a \in M\} \). A subset \( \mathcal{F} = \{f_1, \ldots, f_l\} \) of \( M \) is called a standard basis of \( M \) (w.r.t. \( < \)) if

\[
\text{in}(\{f_1, \ldots, f_l\}) = \langle \text{in}(f_1), \ldots, \text{in}(f_l) \rangle.
\]

Consider a \( k[[x]] \)-linear map \( \ell : k[[x]]^m \rightarrow k[[x]]^p \); \( a = (a^1, \ldots, a^m) \mapsto \sum_{i=1}^m f_i a^i \). Assume that \( f_1, \ldots, f_m \) form a standard basis for \( \text{im}(\ell) \). Choose a partition of \( S = \text{supp}(\text{in}(\text{im}(\ell))) \subseteq \mathbb{N}^n \times \{1, \ldots, p\} \) by disjoint sets \( S_1, \ldots, S_m \), such that \( S_i \subseteq \text{supp}(k[[x]] \cdot \text{in}(f_i)) \). For a subset \( A \) of \( \mathbb{N}^n \times \{1, \ldots, p\} \) we will consider the projection \( p_1(A) \) onto the first factor \( p_1(A) := \{\alpha \in \mathbb{N}^n ; \exists j \in \{1, \ldots, p\} : (\alpha,j) \in A\} \). Moreover, set

\[
\Delta(\ell) := \{b \in k[[x]]^p ; \text{supp}(b) \cap \text{supp}(\text{in}(\ell)) = \emptyset\}
\]

and

\[
\nabla(\ell) := \{a \in k[[x]]^m ; \text{supp}(a,f_i) \subseteq S_i \text{ for all } i\}.
\]

With \( \ell^0 : k[[x]]^m \rightarrow k[[x]]^p ; a \mapsto \sum_i \text{in}(f_i) a^i \) this means

\[
k[[x]]^m = \ker(\ell^0) \oplus \nabla(\ell) \text{ and } k[[x]]^p = \text{im}(\ell^0) \oplus \Delta(\ell).
\]

As the next theorem shows even more is true: This decomposition still holds with \( \ell^0 \) replaced by \( \ell \).
1.2. SCISSONS OF LINEAR MAPS

Theorem 4. Let \( f_1, \ldots, f_m \in k[[x]]^p \) be a monic standard basis. Denote \( \text{in}(f_i) \) by \( x^{\alpha_{i,j}} \). Let \( S = \bigcup_{i=1}^m S_i \) be a partition of the support of the initial module generated by \( f_1, \ldots, f_m \). Then for all \( f \in k[[x]]^p \) there exist unique quotients \( g_i \in k[[x]] \), \( 1 \leq j \leq m \), and a unique remainder \( h \in k[[x]]^p \) such that

1. \( f = g_1 f_1 + \cdots + g_m f_m + h \) with \( \text{supp}(g_i) \subseteq p_i(S_i) - \alpha^i \) and \( \text{supp}(h) \subseteq \mathbb{N}^n \times \{1, \ldots, p\} \setminus S \).

2. The linear map \( \ell : k[[x]]^m \to k[[x]]^p ; a = (a^1, \ldots, a^m) \mapsto \sum_i a_i f_i^i \) induces a direct sum decomposition

\[
k[[x]]^m = \ker(\ell) \oplus \nabla(\ell) \quad \text{and} \quad k[[x]]^p = \text{im}(\ell) \oplus \Delta(\ell).
\]

For a proof of this theorem we refer to [Gra72], [Hir77], [Gal74], [Gal79], [Sch80] or [HM94]. Using the notation of the theorem, a scission \( \sigma \) of \( \ell \) can be constructed as follows: Denote by \( D_F \) the map

\[
D_F : \text{im}(\ell) \to \nabla(\ell); f \mapsto (g_1, \ldots, g_m).
\]

A projection onto the image of \( \ell \) is given by

\[
\pi : k[[x]]^p \to \text{im}(\ell); f \mapsto f - h.
\]

Then \( \sigma := D_F \circ \pi \) is a scission of \( \ell \).

If \( \mathcal{F} \) doesn’t form a standard basis, we may choose a (monic) standard basis \( \hat{\mathcal{F}} = \{F_1, \ldots, F_l\} \), inducing a \( k[[x]] \)-linear map \( \rho : k[[x]]^l \to k[[x]]^m \) with

\[
\rho_j(a) = \sum_{i=1}^l \beta_{i,j} a_i
\]

where \( F_i = \sum_j \beta_{i,j} f_j \). Thus \( \ell \circ \rho = \hat{\ell} \), where

\[
\hat{\ell} : k[[x]]^l \to k[[x]]^p; a = (a^1, \ldots, a^l) \mapsto \sum_i F_i a^i.
\]

By the preceding remarks \( \tau := D_{\hat{\mathcal{F}}} \circ \pi_{\text{im}(\hat{\ell})} \) is a scission of \( \hat{\ell} \) and thus

\[
\sigma := \rho \tau \pi_{\text{im}(\ell)}
\]

is a scission of \( \ell \). We will refer to this scission of \( \ell \) as the scission of \( \ell \) corresponding to the standard basis \( \hat{\mathcal{F}} \).

Proposition 4. Let \( \ell \) be a \( k[[x]] \)-linear map. Then the scission \( \sigma \) of \( \ell \) corresponding to a standard basis \( \mathcal{F} \) of \( \text{im}(\ell) \) has degree of contraction \( \kappa(\sigma) \) bounded by

\[
\kappa(\sigma) \geq -\max_{f \in \mathcal{F}} \{\text{ord}(f)\}.
\]
Proof. Consider a linear map \( \ell : k[[x]]^n \to k[[x]]^p; a \mapsto \sum_{i=1}^m a_i \) with \( \mathcal{F} = \{ f_1, \ldots, f_m \} \) forming a standard basis of \( \text{im}(\ell) \). Define \( \sigma \) as the scission \( D_{\mathcal{F}} \circ \pi \) of \( \ell \) corresponding to \( \mathcal{F} \). Further, set for \( 1 \leq i \leq m \)

\[
\Delta_i = \{ a \in k[[x]] \mid \text{supp}(a) \subseteq p_1(S_i) - \alpha^i \}
\]

and

\[
\tilde{\Delta} = \{ a \in k[[x]]^p \mid \text{supp}(a) \subseteq \mathbb{N}^n \times \{ 1, \ldots, p \} \setminus S \}.
\]

The division map \( D_{\mathcal{F}} \) is given by (see [Sch80])

\[
D_{\mathcal{F}} = \sum_{k=0}^{\infty} \Phi_1^{-1} \circ (\Phi_2 \circ \Phi_1^{-1})^k.
\]

Here, \( \Phi_1 \) and \( \Phi_2 \) are defined as

\[
\Phi_1 : (\oplus_{i=1}^m \Delta_i) \oplus \tilde{\Delta} \to k[[x]]^p; (g_1, \ldots, g_m, h) \mapsto g_1 x^{\alpha^1+j_1} + \cdots + g_m x^{\alpha^m+j_m}
\]

and

\[
\Phi_2 : (\oplus_{i=1}^m \Delta_i) \oplus \tilde{\Delta} \to k[[x]]^p; (g_1, \ldots, g_m, h) \mapsto g_1 u^1 + \cdots + g_p u^p,
\]

with \( u^i \) given by \( \ell^i = x^{\alpha^i+j_i} - u^i \). After a change of the linear form \( L \) (see [Sch80]) we may assume that \( \text{ord} x^{\alpha^i+j_i} < \text{ord} u^i \). Thus, \( \kappa((\Phi_2 \circ \Phi_1^{-1})^k) \geq 0 \):

\( \Phi_1^{-1} \) operates on a power series \( a \in k[[x]]^p \) by singling out the \( x^{\alpha^i+j_i} \). Hence, \( \text{supp}(\Phi_1^{-1}(a)) \cap p_1(S_i) \subseteq p_1(S_i) - \alpha^i, i = 1, \ldots, m \). The maximal shift is given by the maximal order of the standard basis \( \mathcal{F} \). The second map \( \Phi_2 \) multiplies each component of \( \Phi_1^{-1}(a) \) by a \( u^i \), which has higher order than \( x^{\alpha^i+j_i} \) - the order of \( a \) has increased after applying \( \Phi_2 \circ \Phi_1^{-1} \), which means positive contraction degree! By section 1.1.3

\[
\kappa(D_{\mathcal{F}}) \geq \min_k \{ \kappa(\Phi_1^{-1} \circ (\Phi_2 \circ \Phi_1^{-1})^k) \}.
\]

So \( \kappa(D_{\ell}) = \kappa(\Phi_1^{-1}) = -\max_{f \in \mathcal{F}} \{ \text{ord} f \} \). If \( \mathcal{F} \) is not a standard basis, a scission \( \sigma \) is constructed as in equation (1.3). Then \( \kappa(\sigma) \geq \kappa(\rho) + \kappa(\tau) \geq \kappa(\tau) \). For \( \tau \)
the claim was just proven.

We finish this section with a special \( k[[x]] \)-linear mapping:

Construction 1. Let \( \ell : k[[x]]^n \to k[[x]]^n \) be given by a matrix \( A \in k[[x]]^{n \times n} \) with \( \det A \neq 0 \in k[[x]] \). In this case it is sufficient to use the Weierstrass division theorem instead of Theorem 1. A scission \( \sigma \) for \( \ell \) will be defined by multiplication with \( A^{\alpha_0} \), the adjoint matrix of \( A \), and then taking the quotient by Weierstrass division. For the last step, recall the Weierstrass division theorem: Let \( h \in k[[x]] \), then there exists a linear change of coordinates \( \varphi \) so that \( h \varphi \) is \( x_m \)-regular of order \( \text{ord} h \). The theorem asserts that for any \( g \in k[[x]] \) there exist unique power series \( B, R \in k[[x]] \) such that

\[
h \varphi = B \cdot g + R,
\]
1.2. Scissions of Linear Maps

with \( \deg_{x_n} R < \ord h \). The series \( B_\varphi^{-1} \) is called the quotient of \( h \) by \( g \) using Weierstrass division, and will henceforth be denoted by \( Q(h; \varphi, g) \). Note that \( Q \) is textile.

Let \( y = (y_1, \ldots, y_n)^T \) be defined by \( y = A^{\text{adj}} \cdot z \) for given \( z = (z_1, \ldots, z_n)^T \in k[[x]]^n \). In addition assume that \( \varphi_i \) are linear coordinate changes such that \( y_i \varphi_i \) is \( x_{n'} \)-regular of order \( \ord y_i \). Then we define

\[
\sigma(z) = (Q(y_1, \varphi_1, \det A), \ldots, Q(y_n, \varphi_n, \det A)).
\]

**Proposition 5.** The map \( \sigma \) as defined above is textile and a scission for \( \ell \). Moreover, its degree of contraction is

\[
\kappa(\sigma) \geq -\ord \det A + \kappa(A^{\text{adj}} \cdot (-)).
\]

**Proof.** That \( \sigma \) is textile follows from a proof of the Weierstrass Division theorem. An easy calculation shows that it is indeed a scission and the contraction degree follows from the results in section 1.1. \( \square \)

Note that the last construction differs from the one obtained earlier by means of standard basis. It’s advantage lies in the relative easy computation of its degree of contraction – no estimates on the order of a standard basis of its column module are necessary!

1.2.2 Scissions of arbitrary linear maps

For simplicity of notation we restrict our considerations in this section to textile linear maps on \( A \). All results have generalizations to the multivariate case. An arc \( a \in A \) is a vector of infinite (countable) length. In 1.1.1 textile linear maps \( A \rightarrow A \) were identified with matrices of countable many rows and columns, called \( \mathbb{N}^2 \)-matrices. By definition of textile maps, each row contains just finitely many nonzero entries. We say a matrix \( S \) is a scission of a matrix \( A \), if \( ASA = A \) holds. First consider the case of linear maps between finite dimensional \( k \)-vectorspaces. There, linear algebra provides a simple way of constructing scissions: For example let \( \ell : k^3 \rightarrow k^2 \) be the \( k \)-linear map given by the matrix

\[
A := \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}.
\]

According to the Gauss Algorithm there are matrices \( P \in \text{Gl}_2(k) \) and \( Q \in \text{Gl}_3(k) \) such that \( A \) is equivalent to

\[
\tilde{A} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},
\]

i.e., \( P \tilde{A} Q = \tilde{A} \). \( P \) operates on \( A \) by elementary row operations, \( Q \) by elementary column operations. A scission of \( \tilde{A} \) is given by the matrix

\[
\tilde{S} := \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}.
\]

Indeed, \( \tilde{A} \tilde{S} \tilde{A} = \tilde{A} \). Thus, the matrix \( S := Q \tilde{S} P \) is a scission of \( \ell \). The same reasoning applies for textile linear maps \( \ell : A \rightarrow A \). Two textile linear maps
\( \ell_1, \ell_2 : A \to A \) are called equivalent if there exist linear automorphisms \( P, Q \) of \( A \) such that 

\[
P \ell_1 Q = \ell_2.
\]

Let \( \ell : A \to A \) be a textile linear map. We represent \( \ell \) by an \( N^2 \)-matrix \( (\ell_{ij})_{ij} \) denoted by \( \ell \). Since the maps are textile for all \( i \in \mathbb{N} \) there exists an \( N_i \in \mathbb{N} \) such that \( \ell_{ij} = 0 \) for \( j > N_i \). The submatrix of \( \ell \) obtained by fixing the first index \( i \in \mathbb{N} \) is called the \( i \)th row of \( \ell \). Analogously, the \( j \)th column of \( \ell \) is defined as the submatrix where the second index is fixed to \( j \). The \( N^2 \)-matrix \( \ell \) is said to be in canonical form if all rows and columns contain at most one nonzero entry. Denote by \( \epsilon_{ij} \) the matrix \( (\delta_{ik} \delta_{lj})_{kl} \) with \( \delta_{kl} \) the Kronecker symbol.

Let \( (s_l)_{l \in \mathbb{N}} \) be a sequence of \( N^2 \)-matrices. An \( N^2 \)-matrix \( s \) is the limit of \( (s_l)_{l \in \mathbb{N}} \) if \( s \) is the limit of \( (s_l)_{l \in \mathbb{N}} \) as textile linear maps (see section 1.1.1). This means that for all \( N \in \mathbb{N} \) there exists an \( N_0 \) such that for all \( l \geq N_0 \) the \( j \)th row of \( (s_l - s) \) is zero for \( 0 \leq j \leq N \). In analogy to the notation for power series, we write for the last condition \( \text{ord}(s_l - s_l > N) \).

**Theorem 5.** Every textile linear map \( \ell : A \to A \) is equivalent to a textile linear map in canonical form. The transformation maps \( P, Q \) and the canonical form \( \tilde{\ell} \) are obtained by the algorithm described below.

**Algorithm.**

(i) \( i := 0, \tilde{\ell} := \ell, P := \text{id}, Q := \text{id}; \)

(ii) Set \( N_i := \max\{j; \ell_{ij} \neq 0\} \), w.l.o.g. the pivot element \( \ell_{iN_i} \) equals 1;

(iii) Eliminate the \( (l, N_i) \) entries of \( \ell \) for \( l > i \) by applying

\[
P_i = \text{id} - \sum_{l=1}^{\infty} \ell_{i+l,N_i} \cdot \epsilon_{i+l,i}^{l+1}
\]

from the left;

(iv) Eliminate the \( (i, k) \) entries of \( \ell \) for \( k < N_i \) by applying

\[
Q_i := \text{id} - \sum_{j=0}^{N_i-1} \ell_{i,j} \cdot \epsilon_{i,j}^{N_i,j}
\]

from the right;

(v) Set \( P := P_i \circ P, Q := Q \circ Q_i, \tilde{\ell} := P \circ \ell \circ Q \) and \( i = i + 1 \). Return to (ii).

**Remark.** Note that the constructed \( N^2 \)-matrices \( P \) (resp. \( Q \)) are lower diagonal \( N^2 \)-matrices. Hence the corresponding linear maps \( P \) (resp. \( Q \)) are invertible.

**Example 2.** Consider the difference operator \( \Delta = s^d + h_{d-1}s^{d-1} + \ldots + h_0 \in k[s], \)

\[
s \circ (a_0, a_1, \ldots) = (a_1, a_2, \ldots), \]

with induced map \( \ell : A \to A, \)

\[
a \mapsto \ell(a) = (h_0a_0 + \cdots + h_{d-1}a_{d-1} + a_d, h_0a_1 + \cdots + h_{d-1}a_d + a_{d+1}, \ldots),
\]
1.3. THE RANK THEOREM

for $a \in A$. The algorithm yields as the canonical form of $\ell$

$$a \mapsto \tilde{\ell}(a) = (a_d, a_{d+1}, a_{d+2}, \ldots, a_{d+i}, \ldots).$$

This implies the well known fact that the set of solutions to the equation $\Delta \circ a = b$ is isomorphic to $k^d$.

**Proof.** The finite composition $P_j \circ \cdots \circ P_0$ is denoted by $P^j$ and analogously $Q^j := Q_0 \circ \cdots \circ Q_j$. The sequence $(P^j)_{j \in \mathbb{N}}$ converges to an $\mathbb{N}^2$-matrix $P$, since

$$\text{ord}(P_j - \text{id}) \geq j.$$ 

Thus, $\text{ord}(P^{j+1} - P^j) \geq j + 1$. All $P_j$ are lower diagonal, hence, the same is true for $P$. For $(Q^j)_j$ it is sufficient to show that for all $l \in \mathbb{N}$ there exists an $n_l$ such that for all $m, n > n_l$

$$\text{ord}(Q^m - Q^n) > l.$$ 

Fix an $l \in \mathbb{N}$ and define $n_l$ as a natural number such that all $j \leq l$ appear as the column element of a pivot element $\ell_{rj}, r < n_l$. This gives convergence of $(Q^j)_j$.

The algorithm obviously transforms $\ell$ into its canonical form. 

**Construction 2.** A scission $\sigma$ of a $k$-linear map $\ell : A \to A$ can be constructed as follows: First one reduces to the case of linear maps in canonical form. Assume a scission $\sigma_\ell$ is constructed for the canonical form $\tilde{\ell}$ of $\ell$. A scission of $\ell$ is obtained by $\sigma_\ell := Q \sigma_\ell P$, where $P, Q$ are automorphisms of $A$ with $P/Q = \tilde{\ell}$.

Thus, without loss of generality $\ell$ has matrix representation $\ell$ in canonical form. Denote by $I_1$ the set of indices $i \in \mathbb{N}$ s.t. the $i$th row of $\ell$ is nonzero and by $I_2$ the set of indices $j \in \mathbb{N}$ such that the $j$th column is nonzero. Then

$$\text{im}(\ell) = \{ \gamma \in k^N; \gamma_k = 0 \text{ for all } k \in \mathbb{N} \setminus I_1 \}$$ 

and

$$\ker(\ell) = \{ \gamma \in k^N; \gamma_k = 0 \text{ for all } k \in I_2 \}.$$ 

Then $(\ell|_{\mathcal{L}})^{-1} \circ \pi$ is a scission of $\ell$, where $\pi : k^N \to \text{im}(\ell)$ is the natural projection and $\mathcal{L} := \{ \gamma \in A; \gamma_k = 0 \text{ for } k \in \mathbb{N} \setminus I_2 \}$ is a direct complement of $\ker(\ell)$ as a $k$-vector space.

### 1.3 The Rank Theorem

Consider a textile map $f : C^m \to C^n$ with tangent map $\ell = T_{a_0}f$ at $a_0$. Our purpose is to linearize $f$ locally at $a_0$ by applying local automorphisms of source and target. This is obtained by generalizing the Rank Theorem in [HM94] (proven there for tactile maps) in three directions: We allow textile maps, we give a version with parameters, and also a statement with nilpotent coefficients. The main argument of the proof from [HM94] is recalled and extended to textile maps in section 1.3.1. We introduce textile maps depending on parameters in 1.3.2 and prove the corresponding theorem. The nilpotent case is treated in section 1.3.3.
1.3.1 The Rank Theorem for textile maps

We start with some technical preliminaries. The notation used here is abutted to the analytic case treated in [HM94]. A textile map $\gamma : U \subseteq \mathbb{C} \to \mathbb{C}^m$ is called a curve (over $U$) in $\mathbb{C}^m$. The argument of $\gamma$ is called the parameter of the curve and is mostly denoted by $s$. For an arbitrary subvector space $J \subseteq \mathbb{C}^m$ a textile map $\gamma : U \subseteq \mathbb{C} \to \mathbb{C}^m$ is called a curve in $J$ if $\text{im}(\gamma) \subseteq J$. The set of all curves in $J$ is denoted by $\Gamma(J)$. The tangent space $T_a J$ of $J$ at $a \in J$ is defined as the $k$-vector space with elements $\partial \gamma(0)$, for a curve $\gamma$ in $J$ with $\gamma(0) = a$. Obviously $T_a \mathbb{C}^m$ can be identified with $\mathbb{C}^m$ for any $a \in \mathbb{C}^m$. Thus, a curve in the tangent bundle of $\mathbb{C}^m$ is given by a pair of curves $(\gamma, b) \in \Gamma(\mathbb{C}^m)^2$.

A textile map $f : \mathbb{C}^m \to \mathbb{C}^p$ induces an appropriate tangent map $T_f : T\mathbb{C}^m \to T\mathbb{C}^p$ and further by composition a map

$$\Gamma(T\mathbb{C}^m) \to \Gamma(T\mathbb{C}^p); (\gamma, b) \mapsto (f \gamma, T_f \gamma \cdot b).$$

In the case of tactiles $T_f \gamma \cdot b$ is given by

$$T_f \gamma \cdot b = \sum_{i=1}^{n} (\partial_i f)(\gamma(s)) \cdot b'(s).$$

Let $U \subseteq \mathbb{C}^m$ be an $m$-adic neighbourhood of $a_0 \in \mathbb{C}^m$. Assume that the image $\text{im}(T_{a_0} f)$ has (as a topological vector space) a direct complement $J$, i.e.

$$\text{im}(T_{a_0} f) \oplus J = \mathbb{C}^p.$$ 

Moreover let $\gamma$ be a curve in $U$ with $\gamma(0) = a_0$; then we say $f$ has constant rank at $a_0$ with respect to $J$ if for all curves of the form $(f \gamma, \eta)$ in $T\mathbb{C}^p$ there exist unique curves $\rho$ and $\tau$ such that $(\gamma, \rho)$ defines a curve in $TU$ and $\tau \in \Gamma(TJ)$ with the property

$$\eta = T_f \gamma \cdot \rho + \tau.$$  \hspace{1cm} (1.4)

A textile map $f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p$ is called flat at $a_0$ if for all curves $\gamma$ in $U$ with $\gamma(0) = a_0$ the evaluation at $s = 0$ defines a surjective map $\ker(T_{a_0} f : T_{a_0} U \to T_f a_0 \mathbb{C}^p) \to \ker(T_f : T_{a_0} U \to T_{a_0} f(a_0) \mathbb{C}^p)$.

Similar to [HM94] one proves the following proposition (see [Bru05]):

**Proposition 6.** Let $f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p$ be a textile map of type $f = \ell + h$. Assume there exists a scission of $\ell$, such that $\sigma h$ is contractive. Then $f$ has constant rank at 0 if and only if $f$ is flat at 0.

**Remark.** The contractivity condition on $\sigma$ and $h$ is necessary to conclude that flatness means constant rank. The other direction doesn’t need the construction of a scission of $\ell$. A typical class of flat maps is given by maps with injective tangent map.
1.3. THE RANK THEOREM

Theorem 6 (Rank Theorem). Let \( f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p \) be a textile map on an \( m \)-adic neighbourhood \( U \) of 0 with \( f(0) = 0 \). Write \( f \) in the form \( f = \ell + h \) with \( \ell = T_0 f \) the tangent map of \( f \) at 0. Assume that \( \ell \) admits a scission \( \sigma \) for which \( \sigma h \) is contractive on \( U \), and that \( f \) has constant rank at 0 with respect to \( \ker(\ell \sigma) \). Then there exist locally invertible textile maps \( u : U \to \mathbb{C}^m \) and \( v : f(U) \to \mathbb{C}^p \) at 0 such that

\[
vfu^{-1} = \ell.
\]

Proof. The proof naturally falls into two parts. First construct two invertible textile maps \( u, v \); second show that these maps indeed linearize \( f \). This will be ensured by the rank condition. Set \( u = \text{id}_{\mathbb{C}^m} + \sigma h \). Obviously \( u(0) = 0 \) and \( T_0 u = \text{id} \). By contractiveness of \( \sigma h \) on \( U \) this \( u \) is invertible on \( U \). Note:

\[
\ell \sigma f = \ell \sigma (\ell + h) = \ell + \ell \sigma h = \ell (\text{id} + \sigma h) = \ell u.
\]

Thus, \( fu^{-1} \) fulfills \( \ell \sigma fu^{-1} = \ell \). Without loss of generality one can assume for the rest of the proof that \( \ell \sigma f = \ell \). The second map \( v \) is defined by \( v = \text{id}_{\mathbb{C}^p} - (\text{id}_{\mathbb{C}^p} - \ell \sigma) f \sigma \ell \). Again: \( v(0) = 0 \) and \( v \) is invertible with inverse \( v^{-1} = \text{id}_{\mathbb{C}^p} + (\text{id}_{\mathbb{C}^p} - \ell \sigma) f \sigma \ell \). For later use we write

\[
v = \text{id} - f \sigma \ell + \ell \sigma f \sigma \ell
\]

with \( \kappa(h \sigma) > 0 \). Note: The diffeomorphisms \( u \) and \( v \) are constructed without using the rank condition at all. Assume \( f \) fulfills the equation (*) \( f = f \sigma \ell \). This would imply that

\[
v f = f - (\text{id} - \ell \sigma)f \sigma \ell f
\]

\[
= f - (\text{id} - \ell \sigma)f \sigma \ell
\]

\[
= f - (\text{id} - \ell \sigma)f
\]

\[
= \ell \sigma f
\]

\[
= \ell.
\]

Equation (*) is a consequence of the Rank Condition. The composition \( \sigma \ell \) is a projection onto the complement of \( \ker(\ell) \) in \( \mathbb{C}^m \). It is sufficient to show that \( T_a f|_{\ker(\ell)} = 0 \) for all \( a \in \mathbb{C}^m \) near 0. From \( \ell \sigma f = \ell \) follows \( f = \ell + (\text{id}_{\mathbb{C}^p} - \ell \sigma)f \) and subsequently

\[
T_a f = \ell + (\text{id}_{\mathbb{C}^p} - \ell \sigma)T_a f.
\]

Let \( a \) be fixed in \( U \). Define a curve \( \gamma(s) := s \cdot a \). For \( b \in \ker(\ell) \)

\[
T_{\gamma(s)} f \cdot b = (\text{id}_{\mathbb{C}^p} - \ell \sigma)T_{\gamma(s)} f \cdot b
\]

holds. By uniqueness of the decomposition in equation [1.4]

\[
T_{\gamma(s)} f \cdot b = 0
\]

and thus \( T_a f|_{\ker(\ell)} = 0 \). The assertion follows. \( \Box \)
A textile map \( f = \ell + h \) is called a *quasi-submersion* if
\[
\text{im}(h) \subseteq \text{im}(\ell).
\]
Especially, if \( \ell \) is surjective, \( f \) is a *submersion*. Quasi-submersions play an important role in the applications in section 2. A quasi-submersive map \( f \) is linearizable if the order condition (i.e., there exists a scission \( \sigma \) for \( \ell \) such that \( \kappa(\sigma h) > 0 \)) is fulfilled. Indeed, by construction of \( v \) in the proof of Theorem 6 we see that in the case of quasi-submersive \( f \) this map \( v \) equals the identity. Therefore, checking the Rank Condition becomes obsolete.

Some simplification: The Rank Condition is technical and may be hard to check. In some applications the following simpler condition is sufficient. Let \( f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p \) be a textile map. Denote by \( J \) a direct complement of \( \text{im}(T_0 f) \). Then \( f \) is said to have pointwise constant rank at \( 0 \) with respect to \( J \) if for all \( a \in U \)
\[
\text{im}(T_a f) \oplus J = \mathbb{C}^p.
\]

**Proposition 7.** Let \( f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p \) be a tactile, \( U \) an \( m \)-adic neighbourhood of \( 0 \). If for all \( a \in U \)
\[
\text{in}(\text{im}(T_a f)) = \text{in}(\text{im}(T_0 f))
\]
then \( f \) has pointwise constant rank at \( 0 \) with respect to
\[
\Delta(T_0 f) = \{ b \in \mathbb{C}^p; \text{supp}(b) \cap \text{in}(\text{im}(T_0 f)) = \emptyset \}.
\]

### 1.3.2 The Parametric Rank Theorem

The Rank Theorem ensures linearization of textile maps \( f : U \subseteq \mathbb{C}^m \to \mathbb{C}^p \) of constant rank near a fixed cord \( c \in U \). The Parametric Rank Theorem will deal with families of textile maps, thus providing a tool to trivialize vector bundles (see section 2.1).

Let \( S \subseteq k^q \) be constructible and \( Y \subseteq \mathbb{C}^m \) a subfelt. A map
\[
f_S : S \times Y \to k; (s, c) \mapsto f_S(s, c)
\]
is called a *regular \( k \)-valued family of functions over \( S \) if there is a function \( g : U \times Y \to k \), where \( U \subseteq k^q \) containing \( S \) is a subvariety and \( g \) locally looks like a quotient \( \frac{l}{h} \) of \( h, l \in k[s_1, \ldots, s_q] \otimes_k k[\mathbb{N}^m] \), \( l \) locally non-zero, such that \( g|_{S \times Y} = f_S \). More generally we define a *regular family of textile maps over \( S \) on \( Y \) as a map*
\[
f_S : S \times Y \to \mathbb{C}^p; (s, c) \mapsto (f_{S, \alpha}(s, c))_{\alpha \in \mathbb{N}^{n+1}}
\]
where each \( f_{S, \alpha} \) is a regular \( k \)-valued family over \( S \). Thus for fixed \( s = (s_1, \ldots, s_q) \in S \) the restricted map
\[
f_s := f_S(s, -) : Y \to \mathbb{C}^p
\]
is a (regular) textile map. The \( s_i \) will be referred to as *parameters* and \( S \) as the *parameter space*. If \( f_S \) is a family such that all \( f_s \) are linear maps, we call
it a linear family over $S$. As a special case the family $\text{id}_S : S \times Y \to Y$, where $\text{id}_s = \text{id}$ for all $s \in S$, appears.

If $f_S : S \times C^m \to C^p$ and $g_S : S \times C^q \to C^m$ are two regular families we define their composition as the family $S \times C^q \to C^p$ given by

$$f_S \circ g_S := f_S \circ (\text{proj}_1, g_S),$$

where $\text{proj}_1 : S \times C^q \to S$ is the projection onto the first factor. Thus $(f_S \circ g_S)_s = f_s \circ g_s$. A regular family $f_S : S \times C^m \to C^p$ is called invertible if there exists a regular family $g_S : S \times C^p \to C^m$ over $S$ with $f_S \circ g_S = \text{id}$.

Example 3. Consider

$$\ell_{h_k} : h_k \times A \to A; (s, c) \mapsto (0, sc_0, sc_1, \ldots).$$

Obviously $\ell_{h_k}$ is a regular family. The family $\sigma_S, S = h_k \setminus \{0\}$, defined by

$$\sigma_S : S \times m \cdot A \to A; c \mapsto \frac{1}{s} (c_1, c_2, \ldots)$$

is regular with (right) inverse $\ell|_S$. Thus $\sigma_S$ is an invertible family.

The defining property for contractive textile maps naturally generalizes to families of textile maps over $S$. Let $U = m^i \cdot C^m$ be an $m$-adic neighbourhood of 0. A family $f_S : S \times U \to C^p$ is called contractive on $U$ if it fulfills condition $[1.1]$ independently of $S$, or equivalently, it fulfills $[1.1]$ pointwise: $f_s$ is contractive on $U$ for all $s \in S$.

Theorem 7. Let $f_S : S \times U \to C^m$, $U = m^i \cdot C^m$, an $m$-adic neighbourhood of 0, be a regular family over $S$ with $f_S(-, 0) = 0$. Assume $f_S = \ell_S + h_S$ with $\ell_S : S \times U \to W$ linear with inverse $\ell_S : S \times W \to U$. If $\ell_S \circ h_S$ is contractive on $U$, then $f_S$ admits on $U$ an (right) inverse, i.e., there is a regular family $g_S : S \times f(U) \to C^m$ with $f_S \circ g_S = \text{id}_S$.

Proof. The same reasoning as in the proof of Theorem 2 can be applied in the present situation. The inverse for $f_S$ is constructed as the limit of the sequence defined by the recursion $g^0_S = 0$,

$$g^{i+1}_S = \text{id}_S - h_S \circ g^i_S.$$

By induction one shows that $g^i_S$ is a regular family, the case $i = 0$ being trivial. For $i > 0$: The map $h_S$ is a regular family on $U = m^i \cdot C^m$. Therefore – using the induction hypotheses – we see that $h_S \circ g^{i-1}_S$ is regular and so is $g^i_S$. Moreover, $(\text{ord}(g^{i+1}_S - g^i_S))_i$ is an increasing sequence. Thus the limit of $(g^i_S)_i$ exists and the $\alpha$-coefficient of $g_S, \alpha \in \mathbb{N} \cup \{\infty\}$, is the same as the $\alpha$-coefficient of $g^i_S$ for some $i_\alpha \in \mathbb{N}$, for which we have just shown that it is a regular family.

Consider a regular family $f_S$ on $U \subseteq C^m$. The tangent map with respect to $C^m$ of the family $f_S$ (see section 1.1.2) is the regular family $Tf_S$ given by linear maps $Tf_s$ which are the tangent maps to the $f_s$, $s \in S$. Let $\ell_S : S \times U \to C^p$, $U \subseteq C^m$, be a regular linear family. A scission for $\ell_S$ is a regular linear family $\sigma_S : S \times C^p \to C^m$ such that $\ell_S \sigma_S f_S = \ell_S$.

Assume that $J$ is a direct complement of $\text{im}(T_m f_s)$ in $C^p$, for all $s \in S$, where
a_0 \in U. The family $f_S$ is of constant rank at $a_0$ with respect to $J$ (or fulfills the parametric rank condition at $a_0$ w.r.t. $J$) if for all $s \in S$ the restricted maps $f_s$ are of constant rank at $a_0$ with respect to $J$ (see section 1.3).

**Theorem 8** (Parametric Rank Theorem). Let $f_S : S \times U \rightarrow C^p$ be a regular family, $U = m^t \cdot C^m$; write $f_S = \ell_S + h_S$ with $\ell_S := T_0 f_S$. Assume $f_S(-,0) = 0$ and that the following conditions hold: (i) the linear family $\ell_S$ admits a scission $\sigma_S$ s.t. $\sigma_S h_S$ is contractive; (ii) the family $f_S$ fulfills the parametric rank condition w.r.t. a direct complement of $\text{im}(T_0 f_S)$. Then there exist regular (locally) invertible families $u_S$ and $v_S$ with

$$v_S f_S u_S^{-1} = \ell_S.$$

**Proof.** The arguments used in the proof of Theorem 6 may be applied here. By the assumptions and Theorem 7 the families $u_S = \text{id}_S + \sigma_S h_S$ respectively $v_S = \text{id}_S - (\text{id}_S - \ell_S \sigma_S) f_S \sigma_S \ell_S \sigma_S$ are regular and invertible. By condition (ii) and Theorem 6 these families linearize $f_S$ pointwise, thus

$$v_S f_S u_S^{-1} = \ell_S.$$

1.3.3 The Rank Theorem for test-rings

Let $A$ be test-ring, i.e., a local, commutative, and unital $k$-algebra with nilpotent maximal ideal $n$. Denote by $C_A$ the space of $n$-cords with coefficients in $A$. By Theorem 3 it follows that for a textile map $h : U \subseteq C^m_A \rightarrow C^p_A$ which is contractive with respect to the refined order $\text{ord}$, the map $\text{id} + h$ is invertible. Again $U$ denotes an $m$-adic neighbourhood of 0. The proof of Theorem 6 can be adopted to this setting, thus giving the analogous assertion:

**Theorem 9** (Rank Theorem for test-rings). Let $A$ be a test-ring and $f : U \subseteq C^m_A \rightarrow C^p_A$ be a textile map on an $m$-adic neighbourhood $U$ of 0 with $f(0) = 0$. Write $f$ in the form $f = \ell + h$ with $\ell = T_0 f$ the tangent map of $f$ at 0. Assume that $\ell$ admits a scission $\sigma$ for which $\sigma h$ is contractive on $U$, and that $f$ has constant rank at 0 with respect to $\ker(\ell \sigma)$. Then there exist locally invertible textile maps $u : U \rightarrow C^m_A$ and $v : f(U) \rightarrow C^p_A$ at 0 such that

$$v f u^{-1} = \ell.$$

1.4 The Rank Theorem and Polynomial Rings in Countable Many Variables

The study of textile maps and felts inevitably leads to the investigation of polynomial rings in countably many variables. A felt is the spectrum of the quotient of such a polynomial ring by an ideal, and textile maps are algebra homomorphisms between such (in general) non-Noetherian algebras. We restrict
1.4. RANK THEOREM AND POLYNOMIAL RINGS

our attention mostly to felts defined by tactile maps, especially including the situation as it appears in Denef-Loeser’s local triviality result, see Lemma 10. Section 1.4.1 starts with the definition of polynomial and – in preparation for chapter 3 – formal power series rings in infinitely many variables as it can be found in [Bou98]. Afterwards, in section 1.4.2 an inverse mapping theorem and a rank theorem are proven. These results are extended to felts defined by the solution set of an algebraic system of equations in the ring of generalized formal power series, see section 1.4.2:

1.4.1 Polynomial rings in countable many variables

Let $S$ be a monoid with composition written multiplicatively). For a commutative ring $A$ we consider $A(S)$, the $A$-module of formal linear combinations of elements of $S$ with coefficients in $A$. A basis for $A(S)$ is given by elements $e_s: t \mapsto \delta_{st}$, where $\delta$ is the Kronecker-$\delta$. So every element of $A(S)$ can be written uniquely as

$$\sum_{s \in S} \alpha_s e_s$$

for $\alpha_s \in A$, just finitely many non-zero. The $A$-module $A(S)$ obviously becomes an associative $A$-algebra with multiplication defined by

$$e_s \cdot e_t := e_{st}.$$ 

Moreover, if $A$ is commutative so is $A(S)$. This algebra is called the $A$-algebra of the monoid $S$, see [Bou89], III.2.6.

Example 4. Consider $S = \mathbb{N}(I)$ where $I$ is an arbitrary index set. In this case $A(S)$ is also called the free commutative associative algebra of $I$ over $A$. It will be denoted by $A[x_i; i \in I]$ and is also known as the $A$-algebra of polynomials in variables $x_i, i \in I$.

For arbitrary elements $x = \sum s x_s e_s, y = \sum s y_s e_s \in A(S)$ their product can be written as

$$xy = \sum_{s \in S} \left( \sum_{ut=s} x_u y_t \right) e_s.$$  \hspace{1cm} (1.5)

Formula (1.5) even makes sense for elements of $A^S$ if for arbitrary $s \in S$ the set

$$\{(u, t) \in S \times S; ut = s\}$$

is finite. Call this property (*). If $S$ has property (*), then $A^S$ becomes an $A$-algebra, too. It is called the total algebra of $S$ over $A$, see [Bou89], III.2.10. The algebra $A(S)$ is a natural subalgebra of $A^S$, and for $T \subseteq S$ a submonoid we can naturally identify $A^T$ as a subalgebra of $A^S$. For an element $x = \sum x_s e_s \in A^S$ we define its support $\text{supp}(x)$ as

$$\text{supp}(x) = \{s \in S; x_s \neq 0\}.$$ 

Example 5. For any set $I$ the monoid $\mathbb{N}(I)$ has property (*), since $\mathbb{N}$ has it. We may thus consider the total algebra of $\mathbb{N}(I)$ over $A$. It is denoted by $A[[x_i; i \in I]]$ or $A[[I]]$ and called the $A$-algebra of formal power series in variables $x_i, i \in I$. 

Proposition 8

Let \( (\phi) \) denote the polynomial ring \( k \) is called contractive of degree \( m \). Then \( f \) is an isomorphism. Without loss of generality we can assume that \( f(x_i) = x_i^l + h_i^q \) with \( h_i^q \in (x_n^1; 1 \leq l \leq m, 0 \leq n \leq i - 1) \subseteq k[i - 1; m] \), i.e., \( l = \text{id} \) and \( h \) is contractive. We inductively construct an inverse for \( f \) by the following sequence of automorphisms: Set \( g_0 = \text{id} \) and assume that automorphisms \( g_1, \ldots, g_{n-1} \) have already been constructed such that \((g_i \circ f)(x_i^l) = x_i^l\).
for \( i \leq l \leq n - 1 \). Define \( g_n : k[N^m] \to k[N^m] \) by

\[
g_n(x_i^j) := \begin{cases} 
  x_i^j - g_{n-1}(h_k^j) & \text{for } i = n \\
  g_{n-1}(x_i^j) & \text{otherwise}
\end{cases}
\]

The sequence \((g_n)_{n\in\mathbb{N}}\) converges since \( g_n(x_i^j) = g_{n+1}(x_i^j) \) for \( i \leq n \), thus its limit defines a textile map \( g : k[N^m] \to k[N^m] \) with \( g(x_i^j) = g_i(x_i^j) \). This \( g \) is the inverse of \( f \). Indeed, for all \( i, j \) we have

\[
(g \circ f)(x_i^j) = g_i(x_i^j) = x_i^j - g_{i-1}(h_i^j) + g_{i-1}(h_i^j) = x_i^j,
\]

where we used the fact that \( h_i^j \) does not depend on \( x_n^j \) with \( n \geq i \).

**Example 6.** Consider \( f : k[N] \to k[N] \) defined by \( x_i \mapsto x_i + \sum_{j<i} x_{j}^j \). Then \( g_2 \) is given by \( g_2(x_0) = x_0, g_2(x_1) = x_1 - x_0^2, g_2(x_2) = x_2 - x_0^2 - (x_1 - x_0^2)^2 \) and \( g_2(x_i) = x_i \) for \( i \geq 3 \) and indeed \( g_2(f(x_i)) = x_i \) for \( i \leq 2 \).

Every \( F \in k[N^m] \) can be written in the form

\[
F = \sum_{\alpha} F_{\alpha} x^\alpha
\]

where the sum is taken over all \( \alpha = (\alpha_{ij})_{ij} \in \mathbb{N}^{(N \times \{1, \ldots, m\})} \), such that all but finitely many \( F_{\alpha} \) vanish. The support \( \text{supp}(F) \) is defined as the set of indices \( \alpha \) such that \( F_{\alpha} \neq 0 \). We say a variable \( x_i^j \) appears in \( F \), and write shortly \( (i,j) \in \text{supp}(F) \), if there exists an \( \alpha \in \text{supp}(F) \) with \( \alpha_{ij} \neq 0 \). If \( F \in k[N^m] \), then we will denote its homogenous part of degree 1 by \( F' \) and the remaining terms \( F - F' \) by \( F'' \).

**Proposition 9** (Rank Theorem). Let \( L \) be a commutative ring with one and \( J = (F_0, F_1, \ldots) \) an ideal contained in \( (x_i^j; i \in \mathbb{N}_0, 1 \leq j \leq m) \subseteq L[N^m] \). Assume that

1. each \( F_{r} \) contains a term \( A_{i_r}^r x_{i_r}^r \) with \( (i_r, j_r) \not\subseteq \cup_{l<r} \text{supp}(F_l) \), \( A_{i_r}^r \in L^\times \) and \( i_{r-1} < i_r \);

2. \( F_{r}' \in L[x_i^j; i < i_r] \).

Then there exists an \( L \)-algebra automorphism \( u : L[N^m] \to L[N^m] \) such that \( u(J) \) is generated by \( F_{r}' \), \( r \in \mathbb{N}_0 \).

**Proof.** We construct the automorphism \( u \) inductively as follows. Set

\[
u_0 : k[N^m] \to k[N^m]; x_i^j \mapsto \begin{cases} 
  x_i^{j_0} - (A_{i_0}^{j_0})^{-1} F_0' & \text{for } (i, j) = (i_0, j_0) \\
  x_i^j & \text{otherwise}
\end{cases}
\]

Clearly \( u_0(F_0) = F_0' \) and \( u_0 \) is an automorphism by Proposition 5, since assumption (2) implies contractiveness of \( u_0 - \text{id} \). Assume that an automorphism \( u_{n-1} \) has been constructed such that \( u_{n-1}(F_r) = F_r' \) for all \( r < n \), and define

\[
u_n : k[N^m] \to k[N^m]; x_i^j \mapsto \begin{cases} 
  x_i^{j_n} - (A_{i_n}^{j_n})^{-1} (u_{n-1}(F_n))'' & \text{for } (i, j) = (i_n, j_n) \\
  u_{n-1}(x_i^j) & \text{otherwise}
\end{cases}
\]

Clearly \( u_n(F_n) = F_n' \) and \( u_n \) is an automorphism by Proposition 5, since assumption (2) implies contractiveness of \( u_n - \text{id} \). Assume that an automorphism \( u_{n-1} \) has been constructed such that \( u_{n-1}(F_r) = F_r' \) for all \( r < n \), and define
Corollary 10. Let \( X \subseteq \mathbb{A}^n \) be a (reduced) hypersurface given by a polynomial \( f \in k[x_1, \ldots, x_m] \) and let \( x(t) \) be a \( k \)-arc of \( X \) which does not lie in \( \text{Sing} X \) up to order \( d \in \mathbb{N} \), i.e., \( e = \min \{ \text{ord}_f(x(t)) \} \leq d - 1 \). Set \( a = x(t) \mod (t)^d \). Then there exists a textile isomorphism \( u : k[\mathbb{N}^m]/m_a \to k[\mathbb{N}^m]/m_a \) such that \( u(1) \) is a linear ideal.
Remark. By the corollary the truncated arc \( a \) can be lifted to an arc \( x(t) \) of \( X \) by solving linear equations. Put differently: The preimage of \( a \) under the truncation map \( x \mapsto x \mod (t)^d \) has the structure of a manifold.

Proof. Taylor expansion yields

\[
f(a + y) = f(a) + \sum_{j=1}^{n} \partial_j f(a) \cdot y^j + h(a; y),
\]

with \( h \) at least of order two in \( y \). Write the \( j \)th component of \( a \) as \( \sum_{i=0}^{d-1} a'_i t^i \), \( a'_i \in k \), and the \( j \)th component of \( y \) as \( \sum_{i>d} x'_i t^i \). By the assumptions the \( F_r \) have non-vanishing linear part (\( N = \max_{j}(\deg \partial_j f(a)) \))

\[
F'_r = \sum_{j=1}^{m} \sum_{1+l+i=r} A'_j x'_i, \quad e \leq l \leq N.
\]

We will consider the class of \( I_\infty \) in the factor ring

\[
R = k[x_i; l \leq d - 1]/m_a[x_i; l \geq d].
\]

Note that the first non-vanishing \( F_r \in R \) has index \( r = e + d \). Indeed since \( x(t) \)

is by assumption an arc of \( X \) its coefficients provide a solution to the equations \( F_r \), \( r \in \mathbb{N}_0 \). Thus all \( F_r \) in which just \( x_i^1 \) with \( i \leq d - 1 \) appear will vanish modulo \( m_a \). For arbitrary \( r < e + d \) the \( F'_r \) depend on \( x_i^1 \) with \( e + i < e + d \), thus on variables with index \( i \leq d - 1 \). Let \( M \) denote the order of \( h \) as a power series in \( y \), by definition of \( h \) we have \( M \geq 2 \). Therefore \( h \) is contractive of degree \((M - 1)d\) and so \( h_r \) depends on \( x_i^1 \) with \( i \leq r - (M - 1)d \). For \( M = 2 \) this bound attains its maximum \( r - d \). If \( r < e + d \) this gives \( i \leq e \), i.e., in \( F_r \) with \( r < e + d \) appear just \( x_i^1 \) with \( i \leq d - 1 \), thus these polynomials vanish in \( R \).

We will apply Proposition \( \text{[2]} \) to \( \overline{T}_\infty \subseteq R \) where \( \overline{F}_r = 0 \) for \( r < e + d \). By assumption there exists a \( p \in \{1, \ldots, m\} \) with \( A'_p \neq 0 \). Assume \( r \geq e + d \). In that case the term \( A'_p x_{r-e}^p \) appears in \( F_r \). By the previous considerations

\[
(r - e, p) \notin \cup_{i<r} \text{supp}(F'_i),
\]

and \( F'_r \), which equals \( h_r \) above, lies in \( k[x_i^1; i < r - e] \). All assumptions of Proposition \( \text{[2]} \) are fulfilled and this gives the desired linearizing isomorphism \( u \).

\[\square\]

Generalized Power Series and their Felts

Let \( G \) be a group with identity element 0. Usually we will write the group operation additively using “+”. A group is called ordered if there is an ordering “\( \leq \)” on \( G \) which is compatible with the group structure, i.e., if \( x \leq y \) then \( x + z \leq y + z \) for all \( z \in G \). The ordering on \( G \) is called total, if it is total as an ordering on a set. From now on we denote by \( G \) a totally ordered group. Any such \( G \) has a natural decomposition into subsets

\[
G_+ = \{ g \in G; g \geq 0 \}
\]
CHAPTER 1. THE RANK THEOREM FOR TEXTILE MAPS

\( G^- = \{ g \in G; g \leq 0 \} \)

with \( G_+ \cap G^- = \{ 0 \} \). The set \( G_+ \) is called the set of positive elements of \( G \), and the elements of \( G^- \) are accordingly called negative. Note that \( G_+ \) is a monoid with “+”, which has the induced total ordering.

In what follows we will restrict to Abelian groups. Further let \( k \) be a field of characteristic 0. We consider formal expressions of the form

\[
\xi = \sum_{g \in G} \xi_g t^g
\]

where \( \xi_g \in k \). The set of all such elements is a \( k \)-vectorspace with coefficientwise addition and \( k \)-multiplication. For an element \( \xi \) of this vectorspace we define the support of \( \xi \) as

\[
\text{supp}(\xi) = \{ g \in G; \xi_g \neq 0 \}.
\]

The coefficient \( \xi_0 \) will be referred to as the constant term of \( \xi \).

**Proposition 11.** Let \( \xi = \sum_{g \in G} \xi_g t^g \) and \( \eta = \sum_{g \in G} \eta_g t^g \) have well-ordered support. Then the multiplication

\[
\left( \sum_{g \in G} \xi_g t^g \right) \cdot \left( \sum_{g \in G} \eta_g t^g \right) = \sum_{g \in G} \left( \sum_{g_1 + g_2 = g} \xi_{g_1} \eta_{g_2} \right) t^g
\]

is well-defined.

For a proof we refer to [vdH01], Prop. 3.1. We define the ring of (formal) \( G \)-series (in one variable \( t \) with coefficients in \( k \)) as the \( k \)-vectorspace

\[
k[[t^G]] = \{ \xi = \sum_{g \in G} \xi_g t^g; \text{supp}(\xi) \text{ is well ordered} \}
\]

together with the ring structure defined in Proposition [11]. In the literature these series are also called generalized power series or Noetherian series. Clearly \( k[[t^G]] \) is commutative with unit element \( t^0 \). We will distinguish the subring \( k[[t^+]] \) of elements of \( k[[t^G]] \) with support contained in \( G_+ \):

\[
k[[t^+]] = \{ \xi \in k[[t^G]]; \text{supp}(\xi) \subseteq G_+ \}.
\]

**Example 8.** For \( n \in \mathbb{N} \) let \( G \) be \((\mathbb{Z}, +, <)\) the additive group of integers with the usual order. Then \( G_+ = \mathbb{N} \) and \( k[[t^+]] \cong k[[t]] \) the ring of formal power series in \( t \).

The following Proposition collects some simple properties of these rings:

**Proposition 12.** (1) Every \( \xi \in k[[t^G]] \) has a unique representation of the form \( \xi = ct^w(1 + \eta) \) with \( c \in k \), \( w \in G \) and \( \eta \in k[[t^+]] \).

(2) The ring \( k[[t^+]] \) is a local domain with maximal ideal \( m = (t^g; g > 0) \) and \( k[[t^G]] \) is a field.

The ring \( k[[t^+]] \) is endowed with a topology given by the \( G \)-valuation

\[
v: k[[t^G]] \rightarrow G; v(\xi) = \min \text{supp}(\xi).
\]
The neighbourhoods of 0 are given by the ideals \( U_g = \{ \xi \in k[[t^+]] \mid v(\xi) \geq g \}, g \in G_+ \).

We briefly recall the concept of transfinite induction. Let \( \mathcal{N} \) be a well-ordered set and \( A \subseteq \mathcal{N} \). If for every \( g \in \mathcal{N} \) the fact that \( o \in A \) for all \( o < g \) implies \( g \in A \), then \( A = \mathcal{N} \). In other words: If some property \( P \) holds for \( \min \mathcal{N} \) and if from the fact that \( P \) holds for all \( o < g \) follows that \( g \) has \( P \), then \( P \) holds for all \( g \in \mathcal{N} \).

A map \( \varphi : k[[t^+]]^m \to k[[t^+]] \) is called textile if for any \( \xi = (\xi_1, \ldots, \xi_m) \in k[[t^+]]^m \), \( \xi^j = \sum_{g \in G} \xi^j_g t^g \), the image \( \varphi(\xi) = \sum_{g \in G} \varphi_g(\xi) t^g \) is a \( G \)-series with \( \varphi_g(\xi) \) polynomial in a finite number of \( \xi^j_g \), \( 1 \leq j \leq m \), and \( g \in G \). We call \( \varphi \) tactile if it is induced by some polynomial expression, i.e., if there exists a polynomial \( f \in k[x_1, \ldots, x_m] \) such that \( \varphi(\xi) = f(\xi_1, \ldots, \xi_m) \). Tactile maps are clearly textile. Note that though we demand that \( \varphi_g(\xi) \) is polynomial for all \( \xi \), we cannot in general identify \( \varphi_g \) with a polynomial. If we restrict to elements with support contained in a fixed well-ordered submonoid of \( G_+ \), then we may identify \( \varphi_g \) with a polynomial.

Let \( \mathcal{N} \subseteq G_+ \) be a submonoid, which is well-ordered in the induced ordering. Set \( w = \min \mathcal{N} \). Then we consider the subalgebra \( k[[\mathcal{N}^w]] \subseteq k[[t^+]] \) of \( \mathcal{N} \)-series given by elements \( \xi \) with \( \text{supp}(\xi) \subseteq \mathcal{N} \). A polynomial \( f \in k[x_1, \ldots, x_m] \) defines a hypersurface \( X \subseteq \mathbb{A}^m \) and a tactile map

\[
\varphi : k[[\mathcal{N}^w]]^m \to k[[t^+]]; \xi \mapsto f(\xi).
\]

The image of a vector \( \xi \) of \( \mathcal{N} \)-series can be written as \( \varphi(\xi) = \sum_{g \in \mathcal{N}} \varphi_g(\xi) t^g \) with \( \varphi_g(x) \) being a polynomial in the indeterminates \( x^j_g, 1 \leq j \leq m, g \in \mathcal{N} \).

The coefficients \( F_g = \varphi_g(x) \) define an ideal \( I \) in

\[
k[\mathcal{N}^w] = k[x^j_g; 1 \leq j \leq m, g \in \mathcal{N}].
\]

This gives a subscheme \( X_{\mathcal{N}} = \text{Spec} k[\mathcal{N}^w]/I \) of \( \mathbb{A}^m_{\mathcal{N}} = \text{Spec} k[\mathcal{N}^w] \). In this framework a textile map \( \mathcal{N}_{\mathcal{N}} \to \mathcal{N}^w \) is just a \( k \)-algebra homomorphism

\[
\varphi : k[\mathcal{N}^w] \to k[\mathcal{N}^w].
\]

Especially \( \varphi \) is called contractive, if for all \( g \in \mathcal{N} \) the \( \varphi_g(x) \) is polynomial in \( x^j_o \) with \( o < g \).

Remark. In the case \( \mathcal{N} = \mathbb{N} \) the arc space \( X_\infty = X_{\mathbb{N}} \) is defined as the projective limit of the jet spaces of \( X \). Recall that the \( p \)th jet space \( X_p \) of \( X \) is defined as the set of truncated polynomial solutions (of degree \( p \) in one variable, say \( t \)) to the defining equations of \( X \). That is, for \( X = V(f) \subseteq \mathbb{A}^m \) we have

\[
X_p(k) = \{ x(t) \in (k[t]/(t^{p+1}))^m \mid f(x(t)) = 0 \mod t^{p+1}) \}.
\]

It is easy to see that \( X_p \) is a \( k \)-scheme of finite type! In the situation of arbitrary \( \mathcal{N} \) or \( k[[t^+]] \) it is a priori not clear how to define an analog for the \( X_p \) having nice properties like being of finite type over \( k \). A generalization of the jet scheme construction could be to set for \( g \in G_+ \)

\[
X_g = \text{Spec} k[x^j_o; 1 \leq j \leq m, o < g]/(F_o; o < g),
\]
which respects the topology induced by the valuation $v$. But there is one major drawback - the $X_g$ need not be of finite type. Take $\mathcal{N}$ to be the monoid generated by \( \left( \frac{n-1}{n}; n \in \mathbb{N} \right) \subseteq \mathbb{Q} \) and 1. For $g = 1$

\[
X_1 = \text{Spec } k[x_g^j; 1 \leq j \leq m; 0 < g]/(F_o; o < 1)
\]
and this is the spectrum of a polynomial ring in infinitely many variables.

**Proposition 13.** Let $f : \mathbb{A}^m_{\mathcal{N}} \to \mathbb{A}^m_{\mathcal{N}}$ be a textile map of the form $f = \ell + h$ with $\ell$ a linear isomorphism and $\ell^{-1} h$ contractive. Moreover assume that $f(0) = 0$. Then $f$ is an isomorphism.

**Proof.** Without loss of generality $\ell = \text{id}$ and $h$ is contractive, i.e.,

\[
h_{ij} \in (x^l_o; 1 \leq l \leq m, w \leq o < g) \subseteq k[x^l_o; 1 \leq l \leq m, w \leq o < g],
\]
for all $(g,j) \in \mathcal{N} \times \{1, \ldots, m\}$. We inductively construct an inverse for $f$ by the following sequence of ring automorphisms: Set $u_0 = \text{id}$ and assume for $o < g$ automorphisms $u_o$ have already been constructed such that $(u_o \circ f)(x^j_o) = x^j_o$ for $\omega \leq o$. Define $u_g : k[\mathcal{N}^m] \to k[\mathcal{N}^m]$ by

\[
u_g(x^j_o) := \begin{cases} x^j_o - u_p(h^j_o) & \text{for } o = g \\ u_o(x^j_o) & \text{for } o < g, \\ x^j_o & \text{otherwise} \end{cases}
\]

where $p \in \mathcal{N}$ is the maximal index $\omega$ of an $x^j_o$ appearing in $h^j_o$. Since $h$ is contractive $p < g$. The sequence $(u_g)_{g \in \mathcal{N}}$ converges since $u_g(x^j_o) = u_s(x^j_o)$ for $o \leq g$ and $s > g$, thus defining a textile map $u : k[\mathcal{N}^m] \to k[\mathcal{N}^m]$ with $u(x^j_o) = u_g(x^j_o)$. This $u$ is the inverse of $f$. Indeed for all $g,j$ we have

\[
(u \circ f)(x^j_o) = u_g(x^j_o) + u_g(h^j_o) = x^j_o - u_p(h^j_o) + u_p(h^j_o) = x^j_o.
\]

As in the previous section we will write $F'$ for the homogenous part of degree 1 of an element $F \in L[\mathcal{N}^m]$, set $F'' = F - F'$ and define the support of a polynomial $F \in k[\mathcal{N}^m]$ analogously to the definition in the classical setting.

**Proposition 14.** Let $L$ be a commutative ring with one and $J = (F_g; g \in \mathcal{N})$ in $L[\mathcal{N}^m]$ an ideal in $(x^l_o, o \in \mathcal{N}, 1 \leq j \leq m) \subseteq k[\mathcal{N}^m]$. Assume that

1. every $F'_g$ contains a term $A^{\omega_g}_{j_g} x^j_o \omega_g$ such that $(\omega_g, j_g) \not\in \cup_{o < g} \text{supp}(F'_o)$,

2. $A^{\omega_o}_{j_o} \in L^x$ and $\omega_o < \omega_g$ for $o < g$;

3. $F''_g \in L[x^l_o; o < \omega_g]$.

Then there exists an $L$-algebra automorphism $u : L[\mathcal{N}^m] \to L[\mathcal{N}^m]$ such that $u(J)$ is generated by $F'_g$, $g \in \mathcal{N}$.

**Proof.** We proceed analogously to the proof of Proposition 9 and construct the automorphism $u$ inductively as follows. Set

\[
u_o : L[\mathcal{N}^m] \to L[\mathcal{N}^m]; x^j_o \mapsto \begin{cases} x^j_o & \text{for } 0 < j \leq m \text{ and } \omega_o < \omega_g, \\ x^j_o - (A^{\omega_o}_{j_o})^{-1} F'' & \text{for } (o, j) = (\omega_o, j_o) \text{ otherwise.}
\]

\]
Clearly $u_w(F_w) = F'_w$ and $u_w$ is an automorphism by Lemma 3 since $\tilde{\text{supp}}(F'_w) \subseteq \{(o, j) : o < \omega_o\}$. Assume that for all $o < g$ the automorphisms $u_o$ have been constructed such that $u_o(F_{\eta}) = F'_{\eta}$ for all $\eta \leq o$. Then we define

$$u_g : x^j_{\eta} \mapsto \begin{cases} x^j_{\omega_g} - (A^j_{\omega_g})^{-1} (u_{p_g}(F_g))'' & (\eta, j) = (\omega_g, j_g) \\ u_{\eta}(x^j_{\eta}) & (\eta, j) = (\omega_o, j_o) \text{ for some } o < g \\ x^j_{\eta} & \text{otherwise.} \end{cases}$$

Here $p_g$ is the maximal index $o$ of elements $x^j_o$ appearing in $F_g$. By the induction hypothesis for $o < g$ we have $u_g(F_{\eta}) = u_{p_o}(F_{\eta}) = F'_{\eta}$. Moreover

$$u_g(F_g) = u_{p_g}(F_g) - (u_{p_g}(F_g))'' = F'_g.$$  

The last equality follows from the fact that the $u_o$ have linear part equal to the identity. Using Lemma 13 we see $u_g$ is invertible: if $(o, j) \in \tilde{\text{supp}}(u_{p_g}(F_g))''$ then $o < \omega_g$. The $(u_o)_o$ converge towards an automorphism of $L[N^m]$ since

$$u_g(x^j_o) = u_{p'}(x^j_o)$$

if $\omega_g, \omega_{n'} \geq o$ and the sequence $(\omega_r)_r$ is increasing. This completes the proof. □
Chapter 2

Six instances of the linearization principle

With the preparations presented in Chapter 1 we are now ready to prove and partially extend the following six results in singularity theory by one argument (namely the Linearization Principle): Denef-Loeser’s local-triviality result for arc spaces [DL99], the Grinberg-Kazhdan-Drinfeld formal arc theorem [GK00, Dri02], triviality of the solution space of certain polynomial differential operators, Tougeron’s Implicit Function Theorem [Tou68], Artin’s respectively Wavrik’s Approximation Theorem [Art68, Wav75], and an inversion theorem by Lamel-Mir [LM07].

Recall that \( \mathcal{O} \) and \( \mathcal{A} \) denote the \( k \)-algebras of \( n \) respectively 1 cords. In the latter case we speak of arcs. They naturally identify with elements of \( k[[t]] \) respectively \( k[[t]] \).

2.1 A fibration theorem by Denef and Loeser

Let \( X \subseteq \mathcal{A}^n \) be an affine variety over a field \( k \) of characteristic 0 defined by elements \( f_1, \ldots, f_p \) of \( k[x_1, \ldots, x_n] \). These polynomials define by substitution of power series \( a_i \in k[[t]] \) for the \( x_i \) a tactile map \( F : \mathcal{A}^n \to \mathcal{A}^p \) with coefficients \( (F_i) \in \mathbb{N} \). The felt defined by \( F \) is called the arc space of \( X \) and denoted by \( X_\infty \).

In terms of power series

\[
X_\infty = \{ a = (a^1, \ldots, a^n) \in k[[t]^n; f_1(a) = \ldots = f_p(a) = 0 \}
\]

For \( q \in \mathbb{N} \) we write \( \pi_q \) for the natural projection \( X_\infty \to (\mathcal{A}/m_q^{q+1})^n \cong (k^{q+1})^n \) sending an arc \( a \) to the vector of its first \( q + 1 \) coefficient-vectors \( (a_0, \ldots, a_q) \).

The image of \( X_\infty \) under \( \pi_q \) is contained in

\[
X_q = \{ a = (a_0, \ldots, a_q) \in (k^n)^{q+1}; F_0(a) = \ldots = F_q(a) = 0 \},
\]

the set of “approximate solutions” called the \( q \)th jet-space of \( X \). Note: \( \pi_q(X_\infty) \) consists of those approximate solutions which can be lifted to (exact) solutions in \( \mathcal{A}^n \). For an element \( g \in k[x_1, \ldots, x_n] \) and an arc \( a \in \mathcal{A}^n \) we define the order of \( a \) with respect to \( g \) as

\[
\text{ord}_g(a) := \text{ord}(g(a)).
\]
Here \( g(a) \) is obtained by substituting \( a^i \) for \( x_i \) in \( g \). Let \( I \subseteq k[x_1, \ldots, x_n] \) be an ideal. The order of \( a \) with respect to \( I \) is defined as
\[
\text{ord}_I(a) := \min\{\text{ord}_I g; g \in I\}.
\]

Especially if \( I \) denotes the ideal of \( \text{Sing}(X) \), we will write \( A_e(X) \), \( e \in \mathbb{N} \), for the set of arcs on \( X \) lying in \( \text{Sing}(X) \) with order at most \( e \), i.e.,
\[
A_e(X) = \{a \in X_\infty; \text{ord}_I(a) \leq e\}.
\]

**Theorem 10.** ([DL99], Lemma 4.1) Let \( X \) be an affine algebraic variety over \( k \) of pure dimension \( d \); let \( e \in \mathbb{N} \). The map
\[
\pi_e : X_\infty \rightarrow \pi_e(X_\infty) \subseteq (k^n)^{e+1}
\]
is a piecewise trivial fibration over \( \pi_e(A_e(X)) \) with fibre \( m^{e+1} \cdot A^d \). This means: \( \pi_e(A_e(X)) \) can be covered by finitely many locally (Zariski-) closed subsets \( S \) such that there exist textile invertible maps \( \varphi \) with commutative diagram
\[
\begin{align*}
\pi_e^{-1}(S) \xrightarrow{\varphi} S \times (m^{e+1} \cdot A^d) \\
\downarrow \pi_e \downarrow \downarrow \downarrow \downarrow \\
S \xrightarrow{\text{proj}_1} S
\end{align*}
\]

This result implies Lemma 4.1 in [DL99]: the trivializing textile map \( \varphi \) is by construction (see below) compatible with the truncation maps \( \pi_q \), respectively \( \pi_q \), \( q \geq p \), as described in section 1.1.1, thus inducing a trivial fibration \( \pi_{q+1}(X_\infty) \rightarrow \pi_q(X_\infty) \), \( q \geq e \), over \( \pi_q(A_e(X)) \) (with respective affine bundle structure) in the sense of [DL99]. The proof of Theorem 10 will be given in the next two sections.

The proof of the trivialization of \( \pi_e \) in [DL99] and [Loo02] makes use of Hensel’s Lemma (see e.g. Corollary 1 in III, §4.5 of [Bou98]), which in turn follows from Thm. 2, III, §4.5 there. Notice that the statement of this Thm. 2 is analogous to the Rank Theorem in the respective setting. Our proof of Thm. 10 gives in addition an explicit description of the trivializing map \( \varphi \).

### 2.1.1 The Hypersurface Case

Let \( X = V(f) \subseteq \mathbb{A}^n_k \) with \( f \in k[x_1, \ldots, x_n] \) be a (reduced) hypersurface. The singular locus \( \text{Sing}(X) \) is given by the Jacobian ideal
\[
J_f = (f, \partial_1 f, \ldots, \partial_n f).
\]

Each \( a \in A_e(X) \) can be decomposed as \( a = \bar{a} + \hat{a} \) where \( \bar{a} \) denotes the arc \( (a_0, \ldots, a_e, 0, \ldots) \) and \( \hat{a} = a - \bar{a} \). Thus, \( \text{ord}(\hat{a}) \geq e + 1 \). We identify \( \bar{a} \) with the element \( \pi_e(a) \). The polynomial \( f \) induces a tactile \( A^e \rightarrow A \). We view \( f \) as a
regular family over the parameter set $\mathcal{S} = \pi_e(A_e(X))$, which is constructible, see e.g. [Reg95], §1, or section (4.4) in [DL99]. The parameter set admits a partition into locally closed subsets $S_{i,e'}$ (w.r.t. the Zariski-topology on $\mathbb{A}^{n(e+1)}_k$), $(i, e') \in \Lambda := \{1, \ldots, n\} \times \{0, \ldots, e\}$, defined as

$$S_{i,e'} := \{a \in \pi_e(A_e(X)); \min_j \{\text{ord}(\partial_j f(a))\} = \text{ord}(\partial_i f(a)) = e'\}.$$

Consider for $\alpha \in \Lambda$ the family $f_{S_{\alpha}}: S_{\alpha} \times \mathbb{A}^{e+1} \to \mathcal{A}; (\bar{a}, \eta) \mapsto f(\bar{a} + \eta)$.

For simplicity of notation we will denote this family again by $f$. Taylor expansion yields

$$f(\bar{a} + \eta) = f(\bar{a}) + \hat{f}(\bar{a}, \eta),$$

where $\hat{f}(\bar{a}, \eta) = \sum \partial_j f(\bar{a}) \cdot \eta_j + h(\bar{a}, \eta)$ defines a regular family on $\mathcal{S}$. The map $h$ is of order at least 2 in $\eta$.

The map $\hat{f}$ fulfills all assumptions of the Parametric Rank Theorem. Its linear part $\ell := T_{\hat{f}}$ has image

$$\text{im}(\ell(\bar{a}, -)) = \langle \partial_i f(\bar{a}) \rangle = \mathbb{A}^{e'+e+1}$$

for all $\bar{a} \in \mathcal{S}$. The image has direct complement $J = \oplus_{i=0}^{e'+e} \mathbb{A}^i$.

Moreover,

$$T_{\hat{f}} \cdot \eta = \sum_j (\partial_j f(\bar{a}) + \partial_j h(\bar{a}, \eta)) \cdot \eta_j$$

and $\text{ord}(\partial_i f(\bar{a}) + \partial_i h(\bar{a}, \varrho)) = \text{ord}(\partial_i f(\bar{a}))$ for all $\varrho \in \mathbb{A}^{e+1}$. Hence, by Proposition [2], $\hat{f}$ fulfills the Rank Condition for all $\bar{a} \in \mathcal{S}$ on $\mathbb{A}^{e+1} \to \mathcal{A}$ (with respect to $J$). By Construction [2] the linear part $\ell$ admits a scission $\sigma$ with contraction degree $\kappa(\sigma) = -e'$ (and complement $\ker \ell \sigma = J$). Indeed, $\sigma$ is constructed by taking the quotient when dividing through $\partial_i f(\bar{a})$ (cf. section 1.2).

Since the division theorem (Theorem 4) requires monic divisors, the coefficients of the family $\sigma = \sigma_\mathcal{S}$ will be rational in the coefficients of $\bar{a}$ but regular on the chosen $\mathcal{S}$. It is easy to see that

$$\kappa(h) \geq 2(e + 1) - (e + 1) = e + 1 > e'.$$

Hence, $\sigma h$ is contractive. The Parametric Rank Theorem gives regular invertible families $u_\mathcal{S}$ and $v_\mathcal{S}$ such that

$$v_\mathcal{S} \hat{f} u_\mathcal{S}^{-1} = \ell_\mathcal{S}.$$

The map $\mathbb{A}^{e+1} \to \mathbb{A}^{e+1}; \eta \mapsto u_\mathcal{S}^{-1}(\eta)$ defines an isomorphism between solutions $x$ of

$$f(\bar{a} + x) = 0$$

and solutions $y$ of

$$\ell(y) = v(-f(\bar{a})).$$
By linear algebra the set of solutions to the last equation is isomorphic to \( \mathfrak{m}^{e+1} \cdot \mathcal{A}^{n-1} \) via a linear map \( \psi : \mathfrak{m}^{e+1} \cdot \mathcal{A}^{n} \to \mathfrak{m}^{e+1} \cdot \mathcal{A}^{n-1} \). This results in the commutative diagram

\[
\begin{array}{ccc}
\pi^{-1}_e(S) & \xrightarrow{\varphi} & S \times \mathfrak{m}^{e+1} \cdot \mathcal{A}^{n-1} \\
\\downarrow{\pi_e} & & \downarrow{\text{proj}_1} \\
S & & S
\end{array}
\]

where \( \varphi \) is the invertible textile map defined by \( \varphi(\bar{a} + \hat{a}) = (\bar{a}, \psi u^{-1}_a(\hat{a})) \).

Consider now the general situation \( S = \bigcup_{\alpha \in \Lambda} S_\alpha \). Then for each \( \alpha \in \Lambda \) there exists a trivializing map \( \varphi_\alpha \). It is a simple matter to check that the transition maps \( \varphi_\alpha \varphi_\beta^{-1} \) are linear isomorphisms for \( \alpha, \beta \in \Lambda \). This completes the proof in the hypersurface case.

### 2.1.2 The General Case

Let \( X \) be an algebraic variety over \( k \) of pure dimension \( d \) defined by the ideal \( \langle f_1, \ldots, f_N \rangle \) in \( k[x_1, \ldots, x_n] \). Its singular locus is given by the ideal \( \langle f_1, \ldots, f_N, \theta \rangle \) where \( \theta \) is running through all \( \left( N - d \right) \)-minors of \( \partial f = \left( \partial f_i \big/ \partial x_j \right)_{ij} \).

In this case \( \mathcal{A}_e(X) \) is the set of arcs \( a \in X_\infty \) for which \( \text{ord}_a(\theta) \leq e \) for at least one \( \left( N - d \right) \)-minor \( \theta \).

We proceed analogously to section 2.1.1 and first show that pointwise linearization is possible. Let \( \bar{a} \) again be the truncation of an arc \( a \in \mathcal{A}_e(X) \) to order \( e \) and consider \( \partial f(\bar{a}) \in k[[t]]^{N \times n} \). Since \( k[[t]] \) is a principal ideal domain, we can find linear automorphisms \( P, Q \) of \( k[[t]]^N \) and \( k[[t]]^n \) such that \( P \partial f(\bar{a}) Q \) is in Smith-form, i.e.,

\[
\begin{pmatrix}
t^{\varepsilon_1} E_1 & 0 & \ldots & 0 & \ldots & 0 \\
0 & \ddots & & \vdots & & \vdots \\
\vdots & & \ddots & E_{N-d} & & \vdots \\
0 & \ldots & \ldots & 0 & \ldots & 0 \\
\vdots & & & \ddots & & \vdots \\
0 & \ldots & \ldots & \ldots & \ldots & 0
\end{pmatrix}
\]

with \( E_i \in k[[t]]^\times \) and \( \varepsilon_1 \leq \ldots \leq \varepsilon_{N-d} \). Endow \( k[[t]]^N \) with the module ordering defined in section 1.2. Then it is clear that the first \( N - d \) columns form a standard basis. Its maximal order is given by \( \varepsilon_{N-d} \). The greatest common divisor of all \( \left( N - d \right) \)-minors of \( \partial f(\bar{a}) \), which is invariant under equivalence of matrices, is equal to \( \prod_i E_i t^{\varepsilon_i} \). Therefore \( \varepsilon_{N-d} \leq e \). Constructing a scission \( \sigma \) for \( \ell(z) = \partial f(\bar{a}) z \) as in section 1.2 thus shows that \( \sigma h \) is contractive. By Proposition 7 we see that the Rank Condition is fulfilled. This gives pointwise linearization of \( \bar{a} \mapsto f(\bar{a} + \hat{a}) \) where \( f = (f_1, \ldots, f_N) \).
We leave it to the reader to verify that one can carry out the same procedure as in section 2.1.1 to prove the local triviality of $\pi : X_\infty \to \pi_e(X_\infty) \subseteq (k^n)^{c+1}$.

### 2.2 The Grinberg-Kazhdan-Drinfeld formal arc theorem

Let $X$ be a scheme of finite type over $k$ and denote by $X_\infty[\gamma_0]$ the formal neighbourhood\(^1\) of the arc space $X_\infty$ in a $k$-arc $\gamma_0$ which does not lie in $(\text{Sing} X)_\infty$. The following theorem is proved for $k = \mathbb{C}$ by Grinberg-Kazhdan in [GK00] and for arbitrary fields $k$ in [Dri02].

**Theorem 11.** Under the above assumptions we have

$$X_\infty[\gamma_0] \cong Y[y] \times D^\infty,$$

where $Y[y]$ is the formal neighbourhood of a (possibly singular) scheme $Y$ of finite type over $k$ in a suitable point $y \in Y$ and $D^\infty$ is a countable product of formal discs, i.e., the formal spectrum\(^2\) of $k[[t]]$.

**Remark.** Denote the structure sheaf of $X_\infty$ by $O_\infty$. The assertion can be reformulated (see [Reg06]) as

$$\hat{O}_{\infty, \gamma_0} \cong B[z_i; i \in \mathbb{N}]^\wedge.$$ 

Here $B$ denotes a complete local Noetherian ring (corresponding to $Y[y]$) and $B[z_i; i \in \mathbb{N}]^\wedge$ is the completion of $B[z_i; i \in \mathbb{N}]$ w.r.t. the ideal $(z_i; i \in \mathbb{N})$.

We will show that in the case of hypersurfaces this local factorization theorem can be seen as a consequence of the Rank Theorem (over a field of characteristic 0). The restriction to hypersurfaces is not essential but keeps notation simple. The relation between these two results is as follows: As in [Dri02] we use the characterization of the formal neighbourhood by its functor of points from test-rings to sets. A *test-ring* $A$ is a local, commutative, and unital $k$-algebra with nilpotent maximal ideal $n$ and residue field $k$. The $A$-points of $X_\infty[\gamma_0]$ are $A[[t]]$-points of $X$ whose reduction modulo $n$ coincides with $\gamma_0$.

Consider a hypersurface $X$ given by $f \in k[x_1, \ldots, x_n, y]$ where $k$ is a field of characteristic 0. Let $\gamma_0 = (x_0, y_0) \in k[[t]]^{n+1}$ be a $k$-arc of $X$, i.e., $f(\gamma_0) = 0$. Moreover, we assume that $\gamma_0 \notin (\text{Sing} X)_\infty$, thus, w.l.o.g. $\text{ord}_t \partial_y f(x_0, y_0) = d > 0$ (the case $d = 0$ is trivial and will henceforth be excluded). In this setting finding $A$-points for $X_\infty[\gamma_0]$ translates into finding $\gamma = (x, y) \in A[[t]]^n \times A[[t]]$ with $\gamma = \gamma_0 \mod n$ and

$$f(x, y) = 0.$$

---

\(^1\)If $Z$ is a scheme with structure sheaf $O_Z$ and $I$ is an ideal sheaf of a point $p \in Z$, then the formal neighbourhood of $Z$ in $p$, denoted by $Z[p]$, is the topological space $\{p\}$ equipped with the structure sheaf $\lim_{\leftarrow} O_Z/I^n$ (given by $\hat{O}_{Z,p}$); see for example [Har77], Chap. II.9. For the characterization of a formal neighbourhood by its functor of points see the main text.

\(^2\)see [Har77], Chap. II.9.
By the Weierstrass Preparation Theorem there are a unit $u \in A[[t]]^\times$ and a distinguished polynomial $q \in A[t]$, both unique, such that

$$\partial_y f(x, y) = u \cdot q.$$ 

Taking this modulo $n$ shows that $\deg_t q = d$ ($d$ depends on $\gamma_0$ but not on $\gamma$).

For any integer $r > 1$ we define the textile isomorphism

$$\psi_q : A[[t]]^n \to A[[t]]^n \times A[[t]]^{n^2} \times A[[t]] ; (x, y) \mapsto (\bar{x}, \bar{y}, \xi, \eta)$$

induced by Weierstrass division $x = \bar{x} + q^{r+1} \xi$, $y = \bar{y} + q^r \eta$. Now work with $f \circ \psi_q^{-1}$. This will have the advantage that after fixing $\bar{x}$ and $\bar{y}$ the induced map is a quasi-submersion. Note: $\psi_q$ is not textile for general $A$ -- we are strongly using the nilpotency of $n$ in $A$. By Taylor expansion of $\partial_y f(\bar{x} + q^{r+1} \xi, \bar{y} + q^r \eta)$ it is easy to see that

$$\partial_y f(\bar{x}, \bar{y}) = \bar{u} \cdot q$$ (2.1)

for some $\bar{u} \in A[[t]]^\times$. Fixing $\bar{x}$ and $\bar{y}$ consider

$$\varphi : A[[t]]^n \times A[[t]] \to A[[t]] ; (\xi, \eta) \mapsto f(\bar{x} + q^{r+1} \xi, \bar{y} + q^r \eta) - f(\bar{x}, \bar{y}),$$

which has Taylor expansion

$$\varphi(\xi, \eta) = \partial_x f(\bar{x}, \bar{y}) q^{r+1} \cdot \xi + \partial_y f(\bar{x}, \bar{y}) q^r \cdot \eta + H(q^{r+1} \xi, q^r \eta),$$

where $H$ is at least of order two in its entries. Denote the linear part of $\varphi$ by $\ell$. From equation (2.1) we deduce that $\text{im}(\ell) = (q)^{r+1}$ and by construction for $h(\xi, \eta) = H(q^{r+1} \xi, q^r \eta)$ the relation $\text{im}(h) \subseteq \text{im}(\ell)$ holds, i.e., $\varphi$ is quasi-submersive. Therefore we don’t have to check the rank condition. Set $e = \text{ord}_x(q)$ and define $\sigma$ to be the scission for $\ell$ constructed via division by $uq^{r+1}$. It is obvious that the contraction degrees satisfy $\kappa(\ell) = - (r + 1)e$ and $\kappa(h) = 2re$. In the case that $e > 0$ the order condition is fulfilled: $\kappa(h) = 2re > (r + 1)e = \kappa(\sigma)$. If $e = 0$ the situation is more complicated. The composition $\sigma h$ is still contractive with respect to the refined order $\text{ord}$ by Lemma 2. Therefore, the linearizing automorphism $u$ in Thm. 3 can be constructed. This allows linearization of $\varphi$. Solvability of the linearized equation

$$\ell(\xi, \eta) = f(\bar{x}, \bar{y})$$ (2.2)

is given, since by assumption $f(\bar{x}, \bar{y}) \in (q)^{r+1}$. In fact, the solution space to (2.2) is a free $A[[t]]$-module of rank $n$.

Conversely, given $(q, \bar{x}, \bar{y}) \in A[t] \times A[t]_{< d(r+1)} \times A[t]_{< rd}$ fulfilling conditions (C) and equations (E) below, the induced map $\varphi$ is linearizable and the corresponding linear equation (2.2) has a solution. The conditions and equations are as follows:

$$\begin{cases}
C_q & : q = t^d \mod n, q \text{ monic} \\
C_x & : \bar{x} \mod n = x_0 \mod (t)^{d(r+1)} \\
C_y & : \bar{y} \mod n = y_0 \mod (t)^{dr}
\end{cases}$$

and
We are searching for solutions
Taking into account initial conditions follows: Identify again

\begin{align*}
\begin{cases}
E_1: & \partial_y f(\bar{x},\bar{y}) = 0 \mod (q) \\
E_2: & f(\bar{x},\bar{y}) = 0 \mod (q^{q+1}).
\end{cases}
\end{align*}

Indeed, by \((E_1)\) we see that \(\partial_y f(\bar{x},\bar{y}) = B \cdot q\) for some \(B \in A[[t]]\) (here we naturally identify \(\bar{x},\bar{y}\) with elements in \(A[[t]]\)). From \((C)\) it follows that \(B \in A[[t]]^*\). Therefore, \(\im(t) = (q)^{q+1}\); \(\varphi\) fulfills rank and order condition as follows analogously to the presentation above, and the equation

\[\varphi(\xi,\eta) = f(\bar{x},\bar{y})\] (2.3)

has a solution by \((E_2)\). In fact the set of solutions to equation \((2.3)\) is isomorphic to some \(A^q_3\).

To sum up, any \(A\)-deformation of the arc \(\gamma_0\) is determined by \((q,\bar{x},\bar{y})\) fulfilling conditions \((C)\) and \((E)\) and by \((\xi,\eta)\), which have to fulfill a linear equation. The first data defines a scheme \(Y\) of finite type over \(k\). As in \([\text{Dri02}]\) for any \(k\)-algebra \(R\) the set \(Y(R)\) consists of triples \((q,\bar{x},\bar{y})\) fulfilling \((C)\) and \((E)\) (with \(A\) replaced by \(R\)); the distinguished element \(y \in Y\) appearing in the Grinberg-Kazhdan-Drinfeld formal arc theorem corresponds then to \((t^q, x_0 \mod (t^{q+1}), y_0 \mod (t)^q)\).

### 2.3 On solutions of polynomial ODE’s

Textile maps appear naturally in the context of differential and difference equations. For \(q,n \in \mathbb{N}\) and polynomials \(P_i\) in \(qn\) indeterminates we consider the following system of ordinary differential equations:

\[
\begin{cases}
\begin{aligned}
& x_1^{(q)} = P_1(x_1,\ldots,x_n,\frac{d}{dt}x_1,\ldots,\frac{d^{q-1}}{dt}x_1,\ldots,x_n^{(q-1)}) \\
& \vdots \\
& x_n^{(q)} = P_n(x_1,\ldots,x_n,\frac{d}{dt}x_1,\ldots,\frac{d^{q-1}}{dt}x_1,\ldots,x_n^{(q-1)})
\end{aligned}
\end{cases}
\]

We are searching for solutions \(x = (x_1,\ldots,x_n) \in k[[t]]^n\) where \(x_i^{(l)}\) denotes the \(l\)th derivative (with respect to \(t\)) of a power series \(x_i \in k[[t]]\). The problem of finding solutions to this system can be formulated via cords and textile maps as follows: Identify again \(k[[t]]\) with \(A\) and denote by \(D\) the differential operator \(D : A \to A; a = (a_i)_{i \in \mathbb{N}} \mapsto ((i+1)a_{i+1})_{i \in \mathbb{N}}\).

For \(j \in \mathbb{N}\) its \(j\)th power is written as \(D^j\), \(D^0 := \text{id}\). We denote by \(p_i\) the tactile map induced by \(P_i\). Solutions to the system \((*)\) are zeros of the textile map \(f : A^n \to A^n\):

\[f(x_1,\ldots,x_n) = \begin{pmatrix} D^q(x_1) - p_1(x_1,\ldots,x_n,\frac{d^{q-1}}{dt}x_1,\ldots,\frac{d^{q-1}}{dt}x_n) \\ \vdots \\ D^q(x_n) - p_n(x_1,\ldots,x_n,\frac{d^{q-1}}{dt}x_1,\ldots,\frac{d^{q-1}}{dt}x_n) \end{pmatrix}\]

Taking into account initial conditions \(D^j x_i(0) = x_{0,i}, i = 1,\ldots,n, j = 0,\ldots,q-1\) yields a regular family

\[f_{\mathcal{B}} : \mathcal{B} \times (m^q \cdot A^n) \to A^n,\]
where $\mathcal{B} = \mathcal{B}^n$. Denote by $f_{x_0}$ the restricted map $f_{x_0}(x_0, -)$. Zeros of $f_{x_0}$ are solutions of the differential equation with initial condition $x_0 \in \mathcal{B}$.

**Theorem 12.** Solutions of the polynomial differential equation (*) with initial vector $x_0$ are isomorphic to solutions $y \in m^q \cdot A^n$ of a linear system of the form

$$\ell(y) = b_0,$$

where $\ell : A^n \to A^n$ is textile linear and $b_0 \in A^n$.

The proof is mostly a consequence of the following lemma:

**Lemma 15.** (a) Let $\nu_1, \ldots, \nu_p \in \mathbb{N} \cup \{0\}$ and $\mu_1, \ldots, \mu_p \in \mathbb{N}$; the map

$$g : A \to A; x \mapsto (D^\nu x)^{\nu_1} \cdots (D^\nu x)^{\nu_p}$$

has contraction degree $\kappa(g) \geq -\max\{\nu_1, \ldots, \nu_p\}$.

(b) Let $U$ be a neighbourhood of 0 and let $h : U \subseteq A \to A$ be a textile map. Then

$$\kappa(T_0h) \geq \kappa(h).$$

**Proof.** (Lemma) (a) is obvious. For (b): write $h_i$ for the $i$th coefficient of $h$. Then

$$T_0h \cdot y = \partial h \cdot y = \sum_{\gamma \in \mathbb{N}} (\partial h)(0) \cdot y_{\gamma}$$

$$= \left( \sum_{\gamma \leq i + \kappa(h)} (\partial h_i)(0) y_{\gamma} \right)_{i \in \mathbb{N}}.$$

Hence, $\kappa(T_0h) \geq \kappa(h)$.

To prove the theorem we proceed as follows: Using Taylor expansion gives $f_{x_0}$ as $f_{x_0}(y) = f(x_0) + \tilde{f}(x_0; y)$ with $\tilde{f}(x_0; 0) = 0$. This $\tilde{f}(x_0, -) : m^q \cdot A^n \to A^n$ fulfills the assumptions of the Rank Theorem: According to (a) in Lemma 15 $\kappa(\tilde{f}) \geq -(q - 1)$, and further by (b) $\kappa(T_0\tilde{f}) \geq -(q - 1)$ follows. Since $T_0\tilde{f} = D\tilde{f} - T_0p$, we deduce $\kappa(T_0\tilde{f}) = -q$. By Construction 2 there is a scission $\sigma$ for $T_0\tilde{f}$ with $\kappa(\sigma) = +q$. Hence, $\sigma$ composed with $h := f - T_0\tilde{f}$ is contractive. The Rank Condition is fulfilled since $T_0\tilde{f}$ is injective and, thus, flat (see Proposition 3).

By the Rank Theorem there exist linearizing automorphisms $u, v$ such that $v\tilde{f}u^{-1} = \ell$ with $\ell := T_0\tilde{f}$. Similar to section 2.1.1 we conclude that solutions of $\ell(x_0; \eta) = v(-f(x_0))$ are isomorphic to solutions of $f(x_0 + u^{-1}(\eta)) = 0$.

### 2.4 Tougeron’s Implicit Function Theorem

Let $k$ be a complete valued field of characteristic 0. We denote by $k[x, y]$ and $k[[x, y]]$ the ring of convergent and formal power series respectively in the variables $x = (x_1, \ldots, x_n)$ and $y = (y_1, \ldots, y_p)$ with coefficients in $k$. The respective maximal ideals will be denoted by $m$ and $\mathfrak{m}$.

Using Theorem 3 we prove the following result, known as Tougeron’s Implicit Function Theorem (see Proposition 1, p. 206 ff. in [Tou68]):
Theorem 13. Let $F \in k[[x,y]]^q, q \leq p$, with $F(0,0) = 0$. Denote by $A$ the ideal generated by all $q$-minors of the Jacobian $\delta = \partial_y F(x,0)$, and by $B$ any proper ideal in $k[[x]]$. If $F(x,0) \in BA^2$, then there exist $y_1(x), \ldots, y_p(x) \in BA$ such that

$$F(x, y_1(x), \ldots, y_p(x)) = 0.$$ 

An analogous assertion holds for $F \in k\{x,y\}^q$. In that case the $y_i(x)$ will be convergent, too. For simplicity of notation we will restrict our considerations to the hypersurface case, i.e., we assume $q = 1$. We denote the $i$th component of the Jacobian $\delta$ by $\delta_i$. So $A$ is generated by $\delta_1, \ldots, \delta_p$. The proof of the theorem reduces to a proof of the following lemma (see Lemma 3.1 in [Tou68], Lemma 1.2 in Chap. V of [Rui93] or Lemma 2.8 in [Art68]):

Lemma 16. With the notation of the theorem and new indeterminates $y^i = (y^i_1, \ldots, y^i_p), i = 1, \ldots, r$, the following assertion holds: for $r \leq p$ there are power series $Y^i \in k[[x,y^i_1]_l \leq r, 1 \leq j \leq p]^p, 1 \leq i \leq r$, so that

$$F(x, \sum_{i=1}^r \delta_i Y^i) = F(x,0) + \delta \left( \sum_{i=1}^r \delta_i y^i \right)$$

and $Y^i(x,0) = 0$ for $1 \leq i \leq r$.

The lemma obviously asserts that the tactile map

$$g: (y^1, \ldots, y^r) \mapsto F(x, \sum_{i=1}^r \delta_i y^i) - F(x,0)$$

(2.4)

can be linearized. As we know from the introduction, linearizing tactile maps in several variables is not always possible. In the situation of the lemma, however, we work with a quasi-submersion. Indeed, the tactile map $f$ at hand is induced by a rather arbitrary $F \in k[[x,y]]$, in which for $y$ a linear combination of $\delta_i$ is substituted. Thus, the image of $f$ is contained in the image of the tangent map given by $\delta$: $f$ is a quasi-submersion, the Rank Condition is obsolete and linearization is possible as soon as the order condition is fulfilled. Note: the Rank Theorem ensures linearization by tactile maps. Thus we have to check that the linearizing automorphisms obtained from the Rank Theorem in this case are indeed tactile!

Remark. A similar situation appears in the proof of the Grinberg-Kazhdan-Drinfeld formal arc theorem. There a given map is modified in order to become a quasi-submersion by composing it with a linear combination of appropriate power series (related to partial derivatives of the original map), see section 2.2. To prove the theorem it suffices again to work with the modified map.

Remark. More generally Lemma 16 holds for $\delta_1, \ldots, \delta_r \in \text{ann}(M)$ where $M = k[[x]]/\text{im}(\lambda)$ and $\lambda$ is the map induced by the Jacobian $\delta$.

Note that the assumption $F(x,0) \in BA^2$ in Theorem 13 is irrelevant for the linearization described by Lemma 16. However, we will see that it ensures that the linearization of $g$ has a zero: In order to prove Theorem 13 choose generators $\delta_1, \ldots, \delta_r$ of $A$. By Lemma 16 there exist series $Y^i \in k[[x,y^i_1]_l \leq r, 1 \leq j \leq p]^p$ such that

$$F(x, \sum_{i=1}^r \delta_i Y^i) = F(x,0) + \delta \left( \sum_{i=1}^r \delta_i y^i \right).$$
Thus any solution \( y^i \in k[[x]]^p, 1 \leq i \leq r, \) to
\[
F(x, 0) + \delta (\sum_{i=1}^r \delta_i y^i) = 0
\]
(2.5)
yields a solution \( y_1(x), \ldots, y_p(x) \) to \( F(x, y) = 0 \) by setting
\[
y_j(x) = \sum_{i=1}^p \delta_i Y^i_j(x, y^1, \ldots, y^p).
\]
Equation (2.5) is linear. Since \( F \) and thus \( g \) is a tactile map.

\( \text{Proof of Lemma 16:} \) Write \( F(x, y) = F(x, 0) + \delta y + H(x, y) \) where \( H \) is at least quadratic in \( y \); set \( z = (z^1, \ldots, z^r) \). Without loss of generality \( F(x, 0) = 0 \); otherwise consider \( F(x, y) - F(x, 0) \). Define the matrix \( D \) as the \( p \times p \) block matrix \( \text{diag}(\delta_1, \ldots, \delta_r) \), where \( \delta_\sigma = (\delta_1, \ldots, \delta_r) \). Then consider the tangent map
\[
g : k[[x]]^p \to k[[x]]; z \mapsto F(x, D \cdot z).
\]
The tangent map of \( g \) with respect to \( z \) at 0 is given by \( \partial g(0) = \partial F(x, 0) \cdot D \) and thus \( I = \text{im}(\partial g(0)) = \text{im}(\partial F(x, 0) \cdot D) \) is contained in \( I \). So \( \text{im}(g) \subseteq I \). The automorphism \( v \) of Theorem 6 is in this case defined as \( v = \text{id} - (\text{id} - \partial g(0) \sigma) g \sigma \partial g(0) \sigma \) for a scission \( \sigma \) of \( \partial g(0) \). But since \( \text{id} - \partial g(0) \sigma \) is a projection onto the complement of \( I \) we see that \( v = \text{id} \) on \( \text{im}(g) \), i.e., \( g \) has constant rank. In particular \( v \) is a tactile map.

It remains to prove that \( \sigma h \) is contractive. Here we use a scission \( \sigma \) as constructed in section 1.2. For this write \( h(x, z) = \sum_{1 \leq i, j \leq r} \delta_i \delta_j h_{ij}(x, z) \) for appropriate \( h_{ij} \in k[[x, z]] \). Note that in the definition of \( h_{ij} \) we keep track of the order of \( i, j \); this is just a technical convention. The scission \( \sigma \) is given by division through the \( \delta_i \delta_j, 1 \leq i, j \leq r \). Since \( h(x, z) \) has this special form there is a natural way how to divide: \( \sigma h(x, z) \) has on position \( (i-1) \cdot r + j \) the term \( h_{ij} \) and 0 else. It’s easy to see that \( \kappa(\sigma h) > 0 \), since the \( h_{ij}(x, z) \) are at least of order 2 in \( z \in (x_1, \ldots, x_n) \in k[[x]] \). Moreover, \( \text{id} + \sigma h \) is tactile, since the \( h_{ij}(x, z) \) are power series in \( x, z \). Thus the lemma follows from Theorem 6.

2.5 Artin’s and Wavrik’s Approximation Theorem

Let \( F \in k[[x, y]][z] \) with indeterminates \( x = (x_1, \ldots, x_n), y = (y_1, \ldots, y_p) \) and \( z = (z_1, \ldots, z_r) \). We are now interested in solutions \((y(x), z(x)) \in k[[x]]^{p+r} \) to \( F(x, y, z) = 0 \). The solution is called an \( N \)-order solution if
\[
\text{ord } F(x, y(x), z(x)) \geq N + 1.
\]
The following assertion has been proved for $F$ polynomial in \[\text{Art69}\] and for $F$ a power series in \[\text{Wav75}\]: Given a positive integer $q$, there is an $N_0 = N_0(F, q)$ such that any $N$-order solution, $N \geq N_0$, can be approximated to order $q$ by an exact solution. Let us review this theorem in the special case $n = p = m = 1$, $F$ an irreducible polynomial as is proven in Theorem I of \[\text{Wav78}\].

**Theorem 14.** Given $q > 0$ and $F(x, y) \in k[x, y]$ irreducible there exists an $N$ such that if $\bar{y} \in k[[x]]$ satisfies $F(x, \bar{y}) \equiv 0 \mod (x)^N$, then there exists a series $\hat{y}(x) \in k[[x]]$ with $F(x, \hat{y}(x)) = 0$ and $\hat{y}(x) \equiv \bar{y} \mod (x)^q$.

**Proof.** Using the following argument (see \[\text{Wav78}\], proof of Theorem I) we can further assume that $\operatorname{ord}_x \partial_y F(x, \bar{y}) < r \in \mathbb{N}$: Consider the discriminant $\Delta \in k[x]$ of $F$ and $\partial_y F$ and polynomials $A(x, y)$ and $B(x, y)$ such that $\Delta = AF + B\partial_y F$. Denote by $d$ the order of $\Delta$. If $\operatorname{ord} F(x, \bar{y}) > d$ then $\operatorname{ord} \partial_y F(x, \bar{y}) < d$. Take an element $y_0 \in k[[x]]$, $\deg y_0 \leq d$, such that $\operatorname{ord} F(x, y_0) > d + 1$ and $\operatorname{ord} \partial_y F(x, y_0) = e < d$. The textile map $g : (x)^{d+1} \subseteq k[[x]] \to k[[x]]$, $g(z) = F(x, y_0 + z)$ has constant rank, since $\operatorname{im}(F) \subseteq \operatorname{im}(\partial_y F(x, y_0)) = (x)^e$. It is easy to see that $\kappa(\sigma h) > 0$, where $\sigma$ is a scission of $\partial_y F(x, y_0)$ as in section 1.2 and $\kappa h(z) = g(z) - \partial_y g(y_0)z$. Thus we may linearize $g$ at 0 and lift any such $y_0$ to a solution $\hat{y}(x)$ of $f(x, y) = 0$. This linearization is possible as soon as $y_0$ is known up to order $d$.

**Remark.** One should note that the index $N$ obtained in the proof by using the Rank Theorem is much lower than the one provided in \[\text{Wav78}\], p. 411. The proof provided there needed $N = 2d + q$. This follows from the fact that Tougeron’s Implicit Function Theorem is used, which is not as efficient as the Rank Theorem. In a subsequent section of \[\text{Wav78}\] a minimal $N$ is computed by means of resolution of singularities. It is not clear whether this optimal $N$ is the same as the one obtained in the proof above.

### 2.5.1 The Analytic Artin Approximation Theorem

The results of this and the last section give a new view on the proof of Artin’s Approximation Theorem as it was published in \[\text{Art68}\]. In contrast to WAVRIK’s Approximation Theorem by assumption a solution $\bar{y} \in k[[x]]$, and not an approximate solution, to analytic equations in $k\{x, y\}$ is given, and one obtains an analytic solution $\hat{y}$ approximating $\bar{y}$ in the $m$-adic topology. The precise statement is (Theorem 1.2 in \[\text{Art68}\]) as is follows:

**Theorem 15 (Artin’s Analytic Approximation Theorem).** Consider

$$f = (f_1, \ldots, f_q) \in k\{x, y\}^q$$

with $f(0, 0) = 0$. Let $\bar{y} \in k[[x]]^p$ be a formal solution (without constant term) to $f(x, y) = 0$, i.e., $f(x, \bar{y}) = 0$. Then for any $\alpha \geq 1$ there exists a convergent solution $y \in k(x)^p$ of $f(x, y) = 0$ such that

$$y - \bar{y} = 0 \mod m^\alpha.$$

Recall the strategy of proof for Theorem 15 (see for example V.3 in \[\text{Rin93}\] or III.4 in \[\text{Tou68}\] for well-arranged accounts): (i) reduce the general question to a special case with more structure (this involves induction on the height of
I = (f_1, \ldots, f_p) \subseteq k\{x, y\}$. (ii) solve the special case using Tougeron's implicit function theorem (using induction on \(\dim k\{x\}\)).

Denote by \(I\) the ideal generated by \(f_1, \ldots, f_p\) in \(k\{x, y\}\). Then the main reduction steps are:

(A) \(I\) is a prime ideal

(B) \(I = (h_1, \ldots, h_s)\) with \(\delta(x, \bar{y}) \neq 0\) for \(\delta = \det \left( \frac{\partial h_i}{\partial y_j} \right)_{1 \leq i, j \leq s}\).

Consider the reduced case, i.e., assume that (A) and (B) hold. So \(I = (h_1, \ldots, h_s)\) is a prime ideal in \(k\{x, y\}\) and \(\delta(x, \bar{y}) \neq 0\). The series \(h_1, \ldots, h_s\) induce a tactile map \(h: k\{x\}^p \to k\{x\}^s\). If \(\delta_1, \ldots, \delta_r\) are \(s\)-minors of \(\partial_y h(x, 0)\) the modified tactile map

\[(y^1, \ldots, y^r) \mapsto h(x, \sum_{i=1}^r \delta_i y^i)\]

is a quasi-submersion and hence linearizable (compare section 2.4). But the linearized map

\[(y^1, \ldots, y^r) \mapsto h(x, 0) + \partial_y h(x, 0) \left( \sum_{i=1}^r \delta_i y^i \right)\]

does not necessarily have a zero. After an additional modification – this is the assertion of Lemma 17 below – existence of solutions is ensured, and it is sufficient to find an approximating analytic solution to

\[h(x, 0) + \partial_y h(x, 0) \left( \sum_{i=1}^r \delta_i y^i \right) = 0.\]

The last steps are precisely where Tougeron’s implicit function theorem comes into play in the original proof.

**Lemma 17.** Let \(f_1, \ldots, f_p \in k\{x, y\}\), let \(\Delta(x, y) \in k\{x, y\}\), \(\bar{y} \in k[[x]]^p\) such that \(\Delta(0) = 0\), \(\bar{y}(0) = 0\), and \(\Delta(x, \bar{y}) \neq 0\). Suppose that \(f_i(x, \bar{y}) = 0\), \(1 \leq i \leq p\). Then there exist for all \(j \in \mathbb{N}\) a \(z^j \in k\{x\}^p\) with \(y - z = 0\) mod \((x)^j\) such that \(f_i(x, z^j(x)) \in \Delta(x, z^j(x)) \cdot k\{x\}, 1 \leq i \leq p\).

For a proof of this Lemma, which is the crucial part in the proof of Artin’s Approximation Theorem, we refer to [Art68], [Rui93] and [Tou68].

**Remarks.** (a) The proof of Lemma 17 has two parts: (i) it is shown that such a \(z(x)\) exists formally; (ii) there exists a convergent \(z(x)\). For (ii) induction on the number of variables (via Weierstrass division theorem) is used. The assertion of (i) is rather trivial: Write \(\bar{y} = q \cdot \Delta(x, \bar{y})^{\nu+1} + \bar{z}\). By assumption \(\text{ord} \Delta(x, \bar{y}) \geq 1\), so \(\bar{y} - \bar{z} = 0\) mod \((x)^{\nu+1}\). Moreover,

\[0 = f(\bar{y}) = f(\bar{z}) + \partial f(\bar{z}) \cdot q \cdot \Delta^{\nu+1}(x, \bar{y}) + \text{hot},\]

thus \(f(\bar{z}) \in \Delta(x, \bar{y})\). Since \(\Delta(x, \bar{y})\) and \(\Delta(x, \bar{z})\) generate the same ideal in \(k[[x]]\) the formal statement follows (note that for this conclusion the weaker assertion \((\Delta(x, \bar{y})) \subseteq (\Delta(x, \bar{z}))\) would be sufficient).

(b) The convergent \(z(x)\) is obtained by the above mentioned induction on the number of variables, see for example [Tou68] for the details.
2.6 An inversion theorem by Lamel and Mir

In their paper [LM07], Lamel and Mir investigate the group of local holomorphic automorphisms of $\mathbb{C}^n$ preserving a real analytic submanifold $M$ (Cauchy-Riemann automorphisms). Their key result to describe this group is as follows. Denote by $O_N$ the space of holomorphic germs $\mathbb{C}^n \to \mathbb{C}$, and by $\text{Aut}(\mathbb{C}^n,0) \subset O^*_N$ the group of biholomorphic germs of $(\mathbb{C}^n,0)$. An element $f \in O^*_N$ is said to have generic rank $n$ if its Jacobian determinant $\det(\partial f)$ is nonzero as an element in $O_n$. Any $f \in O^*_N$ induces a map $F : \text{Aut}(\mathbb{C}^n,0) \to O^*_N$ given by the composition $u \mapsto f \circ u$.

**Theorem 16.** (Thm. 2.4 in [LM07]) Let $f \in O^*_N$ be a germ of a holomorphic map of generic rank $n$. There exists a holomorphic map $\Psi : O^*_N \times \text{GL}_n(\mathbb{C}) \to \text{Aut}(\mathbb{C}^n,0)$ inverting $F$ in the sense that $\Psi(F(u),\partial u(0)) = u$ for all $u \in \text{Aut}(\mathbb{C}^n,0)$. Furthermore $\Psi$ can be chosen such that $\partial(\Psi(b,\lambda))(0) = \lambda$ for all $b \in O^*_N$ and $\lambda \in \text{GL}_n(\mathbb{C})$.

**Proof.** We shall show how the Rank Theorem allows to construct a suitable $\Psi$ in the formal context taking the space $C_n = \mathbb{C}[x_1,\ldots,x_n]$ of formal power series (cords) instead of $O_n$. In order to treat convergent power series one has to refer to the Rank Theorem from [HM94], with the same reasoning as in the formal case. The argument in [LM07] is much more involved, their computations invoking tacitly various instances of the proof of the Rank Theorem.

The map $F : C^*_n \to C^*_n$ is tactile with Jacobian determinant $\det(\partial f) \neq 0$ in $C_n$. Our goal is to linearize it locally at the linear part $\lambda x$ of a given $u$. Decompose $u \in \text{Aut}(\mathbb{C}^n,0)$ as $u(x) = \lambda \cdot x + v(x)$ with $\lambda \in \text{GL}_n(\mathbb{C})$ and $v \in C^*_n$ of order $2$. Consider the Taylor expansion (with the obvious abbreviation)

$$G(x) = f(u(x)) - f(\lambda x) = \partial f(\lambda x) \cdot v + \partial^2 f(\lambda x) \cdot v^2 + \ldots,$$

with linear part $\ell(v) = \partial f(\lambda x) \cdot v$. Since $f$ is of generic rank $n$ and $\lambda \in \text{GL}_n(\mathbb{C})$, the map $\ell$ is injective. Thus $G$ has constant rank at $0$, by the remark after Proposition [9]. Next we show that $G$ fulfills the order condition of the Rank Theorem (Thm. [3]). In order to keep notation short we assume that $\lambda$ is the identity matrix. Denote the initial form of lowest degree of $f^i$ by $f^i_\lambda$ and write $e_i$ for the order of $f^i$. By the same triangularization argument as in Lemma 4.5 of [LM07] we may assume that $f^i = (f^i_1,\ldots,f^i_n)$ has generic rank $n$. This gives

$$\text{ord} \det(\partial f^i) = e_1 + \ldots + e_n - n.$$

Moreover for $\beta \in \mathbb{N}^n$, $|\beta| = m$, and $l \in \{1,\ldots,n\}$ we have

$$\text{ord}(\partial_{\beta} f^i_l) \geq e_l - m - 1$$

for $e_l \geq m$ and $\text{ord}(\partial_{\beta} f^i_l) = \infty$ else. As the map $f$ has generic rank $n$ a scission $\sigma$ for $\ell$ can be obtained as in Proposition [5] by the adjoint matrix of $\partial f$. The nonlinear part $h = G - \ell$ consists of all terms of $G$ which are of order at least 2 in $v_1,\ldots,v_n$. We write

$$h(v) = \sum_{\alpha \in \mathbb{N}^n, |\alpha| \geq 2} h_\alpha \cdot v^\alpha,$$
with \( h_\alpha \in \mathcal{C}_n^m \). For \( |\alpha| = m \geq 2 \), the coefficient vector \( h_\alpha \) has \( i \)-th component \( h^i_\alpha \) involving the \( m \)-th order partial derivatives of \( f^i \). Multiplication with the adjoint matrix of \( \partial f \) yields in the \( i \)-th component

\[
((\partial f)^{adj} \cdot h_\alpha)_i = \sum_{l=1}^{n} (\partial f)^{adj}_{il} \cdot h^l_\alpha = \sum_{j=1}^{n} (-1)^{i+j} \det(\partial f)^{(l,i)} \cdot h^l_\alpha.
\]

Here, \( A^{(i,j)} \) denotes the \( (n-1) \times (n-1) \) matrix obtained from an \( n \times n \) matrix \( A \) by deleting the \( i \)-th row and the \( j \)-th column. From the last equation it follows that each term in the sum is of type

\[
T = \left( \prod_{1 \leq j \leq n, j \neq l} \partial_i f^j \right) \cdot (\partial \beta f^l),
\]

where \( i, j \in \{1, \ldots, n\} \) and \( \beta \in \mathbb{N}^n, |\beta| = m \). Obviously

\[
\text{ord} T \geq \sum_{i=1}^{n} e_i - n - m + 1.
\]

This allows to compute the contraction degree \( \kappa \) of the map

\[
\varphi_\alpha : v \mapsto \frac{1}{\det(\partial f)} \cdot (\partial f)^{adj} \cdot h_\alpha \cdot v^\alpha
\]

if \( v \) varies in \((x_1, \ldots, x_n)^2 \cdot \mathcal{C}_n^m\). We get

\[
\kappa(\varphi_\alpha) \geq -\left( \sum_{i=1}^{n} e_i - n \right) + \left( \sum_{i=1}^{n} e_i - n - m + 1 \right) + (2m - 2) = m - 1.
\]

So \( \kappa(\varphi_\alpha) > 0 \) for all \( \alpha \) with \( |\alpha| = m \geq 2 \). Now

\[
(\sigma h)(z) = \sum_{\alpha \in \mathbb{N}^n, |\alpha| \geq 2} \varphi_\alpha(z)
\]

yields

\[
\kappa(\sigma h) \geq \min_{\alpha} \kappa(\varphi_\alpha) = 1 > 0.
\]

The order condition is fulfilled. Therefore \( G \) can be linearized to \( \ell \) by local automorphisms of source and target. Once this is done, it suffices to solve the linear equations in order to construct the required map \( \Psi \) of the theorem. \( \square \)
Chapter 3

Jet and Arc Algebras

This chapter contains a collection of partial results and open questions concerning the combinatorial, algebraic and geometric structure of jet and arc algebras (the coordinate rings of affine jet and arc spaces). Section 3.1 introduces these algebras and gives some simple properties. The defining equations for jet and arc algebras can be computed from the defining equations $f_i$ of the base variety using a specific $k$-derivation $D$ on $k[[x_1^j]]$, the polynomial ring in variables $x_i^j$, $1 \leq j \leq m$ and $i \in \mathbb{N}_0$, with coefficients in $k$. We show that this operator $D$ has a canonical form in terms of partial derivatives of the $f_i$’s and the multivariate Bell-Polynomials, see section 3.2. Mustaţa conjectures in [Mus01] that the singular locus of the jet scheme of a local complete intersection is precisely the preimage of the singular locus of the base variety under the canonical projection map. In section 3.3 we discuss some examples and approaches towards this problem. We give a prove for a special case. After this we rise the question for the Poincare series of arc algebras with the grading given by $wt(x_i^j) = i$. For smooth base varieties it turns out to be some power of the generating series of the partition function, section 3.4. We conclude this chapter with some completions of polynomial rings in countably many variables. The ultimate goal would be to describe the generators for the defining ideal of the completion of the local ring of an arc algebra in a given arc. This would be useful for a constructive version of the Grinberg-Kazhdan-Drinfeld formal arc theorem (see section 2.2).

3.1 Definition and Basic Properties

Let $f \in k[x_1, \ldots, x_m]$. For $1 \leq j \leq m$ substitute $\sum_{i=0}^{\infty} x_i^j t^i$ for $x_j$ in $f$ and expand the result as a power series in $t$. It will be of the form

$$f(\sum x_i^j t^i) = \tilde{F}_0 + \tilde{F}_1 t + \tilde{F}_2 t^2 + \ldots,$$

with polynomials $\tilde{F}_i \in k[i; m]$. Recall that $k[i; m]$ was set to be $k[x_i^j; 1 \leq j \leq m, 0 \leq e \leq i]$. Especially, for $i = 0$ we obtain

$$\tilde{F}_0 = f(x_0^1, \ldots, x_0^m).$$

57
Alternatively we may consider the substitution
\[ \varphi : x_j \mapsto \sum_{i=0}^{\infty} x_j^i t^i. \]
Again \( \varphi(f) \) is a power series in \( t \) with coefficients \( F_i \in k[i;m] \). The two families of polynomials are related by
\[ \tilde{F}_i(x_j^i) = F_i(i! x_j^i). \]
The \( F_i \) can also be constructed in the following way: Introduce on \( k[N_m] \) a \( k \)-derivation \( D \) by
\[ D : k[N_m] \to k[N_m]; x_j^i \mapsto D(x_j^i) = x_j^i + 1. \]
The \( i \)-fold composition of \( D \) with itself will be denoted by \( D^i \), and \( D^0 \) is set to be the identity. Using \( D \) the series \( \varphi(f) \) can be rewritten as
\[ \varphi(f) = \sum_{i=0}^{\infty} \frac{D^i F_0}{i!} t^i. \] (3.1)
This is checked on the variables \( x_j \), since both sides are additive and multiplicative in their arguments. By definition, \( \varphi \) is additive and multiplicative. For the right-hand side the generalized Leibniz-rule, i.e.,
\[ D^i(F_0 G_0) = \sum_{l=0}^{i} \binom{i}{l} D^l F_0 \cdot D^{i-l} G_0, \]
implies that
\[ \sum_{i} \frac{1}{i!} D^i(F_0 G_0) t^i = \sum_{i} \sum_{l=0}^{i} \frac{D^l F_0}{i!} \frac{D^{i-l} G_0}{(i-l)!} t^i = \left( \sum_{i} \frac{D^l F_0}{i!} t^i \right) \cdot \left( \sum_{i} \frac{D^l G_0}{i!} t^i \right). \]
From (3.1) we immediately see that
\[ F_i = \frac{1}{i!} D^i F_0. \]

### 3.1.1 The global situation
In what follows we will be mainly interested in the ideal \( (Df) \) generated by the \( F_i, i \in N_0 \). Therefore we will leave out the constant factor \( \frac{1}{i!} \) and use the following notation: \( F_i = D^i f(x_1^i, \ldots, x_n^i) \).

**Remark.** In section 3.2 we will give an even more explicit way to construct the polynomials \( F_i \) by means of multivariate Bell polynomials.

**Example 9.** Consider \( f = y^2 - x^3 \) and write \( a_i \) for \( x_1^i \) and \( b_i \) for \( x_2^i \). Then \( (F_0, F_1, \ldots) \) is given by
\[
(F_0, F_1, \ldots) = (b_0^2 - a_0^3, 2b_0 b_1 - 3a_0^2 a_1, 2b_0 b_2 + 2b_1^2 - 3a_0^2 a_2 - 6a_0 a_3, 2b_0 b_3 + 4b_1 b_2 - 3a_0^2 a_3 - 12a_0 a_1 a_2 - 6a_0^3, \ldots)
\]
There are two canonical gradings on \( k[\mathbb{N}^m] \):

(A) “deg”: each variable has the same degree \( \deg(x_j^i) = 1 \); the \( k \)-vector space of elements of degree \( n \) will be denoted by \( k[\mathbb{N}^m]^{(n)} \).

(B) “wt”: the weight is defined by \( \text{wt}(x_j^i) = i \); thus \( k[\mathbb{N}^m] \) becomes a graded \( k[0;m] \)-algebra. The \( k[0;m] \)-submodule of homogeneous elements of weight \( n \) will be denoted by \( k[\mathbb{N}^m]^{(n)} \).

For any \( F_0 \in k[0;m] \) the derivatives \( D^i F_0 \), \( i \in \mathbb{N} \), are wt-homogeneous of weight \( i \). Especially, the ideal \( (Df) \) introduced above is a weighted homogeneous ideal in \( k[\mathbb{N}^m] \).

Remark. The derivation \( D \) is a derivation of degree 1 with respect to wt, i.e.,
\[
Dk[\mathbb{N}^m]^{(i)} \subseteq k[\mathbb{N}^m]^{(i+1)}.
\]
It is of degree \(-1\) with respect to deg, i.e., \( Dk[\mathbb{N}^m]^{(i)} \subseteq k[\mathbb{N}^m]^{(i-1)} \).

Let \( X \subseteq A_n^m \) be an affine scheme defined by an ideal \( I = (f_1, \ldots, f_p) \subseteq k[x] \). Using the notation introduced above we write \( F_j^i \) for \( D^i f_j(x_1^0, \ldots, x_m^0) \), \( 1 \leq j \leq n \). For \( q \in \mathbb{N} \) the algebras
\[
J_q(X) = k[q;m]/(F_j^i; 1 \leq j \leq n, 0 \leq i \leq q)
\]
respectively
\[
J_\infty(X) = k[\mathbb{N}^m]/(F_j^i; 1 \leq j \leq n, i \in \mathbb{N}_0)
\]
are called the \( q \)th jet and arc algebra of \( X \) respectively. Their associated schemes are called \( q \)th jet space of \( X \) and arc space of \( X \). In the sequel we will write \( (DI) \) for the ideal \( (F_j^i; 1 \leq j \leq n, 0 \leq i \leq q) \).

Proposition 18. Consider two closed subschemes \( X, Y \) of \( k^m \) defined by ideals \( I_X = (f_1, \ldots, f_p) \) and \( I_Y = (g_1, \ldots, g_q) \). Then \( I_X = I_Y \) if and only if \( (DI_X) = (DI_Y) \).

Proof. The direction left to right is trivial. So let us consider the other direction, and assume that \( (DI_X) = (DI_Y) \). For every \( j \in \{1, \ldots, p\} \) we can write
\[
F_j^0 = \sum_{e=1}^q c_e G_e^j.
\]
For weight reasons no other \( G_e^j \) may appear in this expression. By this \( F_j^0 \in I_Y \) for all \( j \), i.e., \( I_X \subseteq I_Y \). Interchanging \( F \)'s and \( G \)'s proves the reverse inclusion and thus the assertion. \( \square \)

Remark. There are examples of schemes \( X \) and \( Y \) which have at all levels isomorphic jet schemes \( X_m \cong Y_m \), \( m \in \mathbb{N} \), but are not isomorphic: \( X \not\cong Y \). In fact, \( X \) and \( Y \) can be chosen to be non-singular, cf. [IW].
Proposition 19. The following properties for elements of $k[N^m]$ hold:

1. If $F \in k[N^m]$ is weighted homogenous and $q_1, \ldots, q_l \in k[N^m]$ are such that $F = q_1 \cdots q_l$, then the $q_i$ are weighted homogenous.

2. Let $F_0 \in k[0;m]$; for all $i \in \mathbb{N}$ the $i$th derivative $F_i$ of $F_0$ is of the form

$$F_i = c_{i,0} \cdot q_i$$

with $\text{wt}(c_{i,0}) = 0$, i.e., it is an element of $k[0;m]$, and $q_i$ irreducible and $\text{wt}$-homogenous of weight $i$. If $o$ and $d$ denote order and degree of $F_0$, then for $i \geq o$ it holds that $c_{i,0}(0) \neq 0$ and for $i \geq d$ that $c_{i,0} \in k$, thus $F_i$ is irreducible.

3. Let $F_0 \in k[0;m]$; then for all $i \in \mathbb{N}_0$: $D^iF_0 \upharpoonright D^{i+1}F_0$ and $D^{i+1}F_0 \upharpoonright D^iF_0$.

Proof. 1. It is sufficient to prove the assertion for $l = 2$. The general assertion then follows by induction. So assume that $f = q_1q_2$. Let $\text{wt}(f) = n$ and let $q_1$ and $q_2$ have order $e_1$ and $e_2$ and degree $d_1$ and $d_2$ respectively with respect to $\text{wt}$. Then $\text{ord}_{wt} q_1q_2 = e_1 + e_2$ and $\text{deg}_{wt} q_1q_2 = d_1 + d_2$. Since $e_i \leq d_i$ we conclude that $e_i = d_i$: if $e_1 < d_1$ then $e_2 > d_2$ which gives a contradiction (analogously we treat the case $e_2 < d_2$). Thus $q_1$ and $q_2$ are weighted homogenous, too.

2. Assume that $F_i = p_1 \cdots p_l$ with $p_i$ irreducible. By 1. we see that the $p_i$ are $\text{wt}$-homogenous. Since $F_i$ is an $i$th derivative there exists a $f \in \{1, \ldots, m\}$ such that $x^i_f$ appears in $F_i$. But then this variable has to appear in one of the $p_e$, say in $p_i$. Thus $\text{wt}(p_i) = i$, $\text{wt}(p_1 \cdots p_{i-1}) = 0$ and we may set $c_{i,0} = p_1 \cdots p_{i-1}$ and $q_i = p_i$.

Next decompose $F_0$ into its $\text{deg}$-homogenous parts $F_0^0 + \cdots + F_0^d$: $\text{deg}(F_0^i) = i$. Then $F_0^i$ contains a term of the form $cx_0^{j_1} \cdots x_i^{j_i}$, $j_i \in \{1, \ldots, m\}$. Applying $D^i$, $i \geq o$ we see that $D^iF_0^i$ is of the form

$$D^iF_0^i = cx_1^{j_1} \cdots x_i^{j_i} \cdots x_{i-(o-1)}^{j_i} + \cdots$$

The first term has degree $o$ and weight $i$, hence appears in $q_i$. Moreover, since $\text{ord} F_i = \text{ord} F_0$ we get

$$o = \text{ord} F_i = \text{ord} c_{i,0} + \text{ord} q_i = \text{ord} c_{i,0} + o$$

which forces $\text{ord} c_{i,0} = 0$. The same argumentation with $\text{deg}$ instead of $\text{ord}$ and $d$ instead of $o$ shows that $\text{deg} c_{i,0} = 0$ for $i \geq d$.

4. The second statement is trivial for weight reasons. For the first assume that the converse holds, i.e., there exists a $q \in k[N^m]$ such that $qF_i = F_{i+1}$. Then necessarily $\text{wt}(q) = 1$, thus $\text{deg}(q) \geq 1$. Since $\text{deg}(F_i) = \text{deg}(F_{i+1})$ we get

$$\text{deg}(F_{i+1}) = 1 + \text{deg}(F_i)$$

a contradiction. \qed

Remark. Note, that 2. holds even if $f$ is reducible.
3.1. DEFINITION AND BASIC PROPERTIES

Example 10. For simplicity of notation we will drop the upper indices and simply write \(x_i\) instead of \(x_i^j\). Accordingly, the expression \(x_i^j\) will denote here the \(j\)th power of the variable \(x_i\).

\[
\begin{align*}
F_0 &= x_0^2(1 + x_0) \\
F_1 &= x_0x_1(2 + 3x_0) \\
F_2 &= 2x_1^2 + 2x_0x_2 + 6x_0x_1^2 + 3x_0^2x_2 \\
F_3 &= 6x_1x_2 + 2x_0x_3 + 6x_1^3 + 18x_0x_1x_2 + 3x_0^2x_3
\end{align*}
\]

The polynomials \(F_2, F_3\) are irreducible. This shows, that irreducibility might already occur earlier than for \(i \geq \deg(F_0)\).

Remark. Many properties of a scheme \(X\) are reflected in properties of its jet schemes \(X_m, m \in \mathbb{N}\), and vice versa. Let \(\mathcal{P}\) be a property of a scheme. For example if \(\mathcal{P}\) is one of the properties “irreducible”, “connected”, “normal” or “\(\mathbb{Q}\)-factorial”, then if \(X_m\) has \(\mathcal{P}\) for some \(m \in \mathbb{N}\), so has \(X\) (cf. [Ish]). Also a scheme \(X\) of finite type over an algebraically closed field (of characteristic 0) is non-singular if and only if there are integers \(m \leq m'\) with flat truncation morphism \(\pi^{m'}_m: X_{m'} \to X_m\), see [Ish].

3.1.2 The local situation

Next we will consider the focussed jet and arc space of a variety \(X\) in a closed point \(p \in X\). For simplicity of notation we restrict our considerations to hypersurfaces through the origin, i.e., \(X = \text{Spec} \ k[x]/(f)\) and \(p\) the origin. Instead of considering all power series (respectively all truncated power series) solutions to the equation \(f = 0\) we restrict to those with vanishing constant terms: \(\sum_{q \geq 1} x_i^q, 1 \leq j \leq m\) and \(q \in \mathbb{N} \cup \{\infty\}\). This corresponds to the following substitution:

\[
(-)^* : k[\mathbb{N}^m] \to k[x_i^j; 1 \leq j \leq m, i \in \mathbb{N}]; x_i^j \mapsto \begin{cases} 0 & i = 0 \\ x_i^j & i \neq 0 \end{cases}.
\]

We will write \((Df)^*\) for the ideal generated by \(F_i^*, i \in \mathbb{N}\). The \(k\)-algebras

\[J_q(X; 0) = \text{Spec} k[x_i^j; 1 \leq i \leq q, 1 \leq j \leq m]/(F_1^*, \ldots, F_q^*)\]

respectively

\[J_\infty(X; 0) = \text{Spec} k[x_i^j; i \in \mathbb{N}, 1 \leq j \leq m]/(Df)^*\]

will be called the focussed qth jet algebra of \(X\) at 0 respectively the focussed arc algebra of \(X\) at 0. The corresponding (affine) schemes will be called focussed qth jet space and focussed arc space of \(X\) at 0.

Note that the above substitution is also well-defined for \(f \in k[[x_1, \ldots, x_m]]\), i.e., it makes sense to speak of the focussed jet space of a formal germ.

Example 11. Consider \(f = y^2 - x^3\) and write \(a_i\) for \(x_i^1\) and \(b_i\) for \(x_i^2\). Then \((Df)^*\) is given by

\[
(Df)^* = (b_1^2, b_1b_2 - a_1^3, \ldots)
\]
For the generators $F_i$ of $(Df)$ we had the simple and useful formula $F_i = DF_{i-1}$.

In the local situation we lose such an expression, but one can recover the defining polynomial (resp. power series) $f$ from the ideal $(Df)^\bullet$. If $g \in k[[x_1^{\infty}]]$ is weighted homogeneous denote by $g[l]$ all terms of $g$ which are built up by variables of weight $l$.

**Proposition 20.** Let $f \in k[[x_1, \ldots, x_m]]$ and $(Df)^\bullet = (F_0^\bullet, F_1^\bullet, \ldots)$. Then:

$$f = \sum_{l=0}^{\infty} \frac{1}{l!} F_l^\bullet [1]$$

*Proof.* Write $f = \sum f_\alpha x^\alpha$. It is clear that $\tilde{F}_i[1] = \sum_{|\alpha|=i} f_\alpha x^\alpha$. Indeed, substitution of $\sum_{j=1}^{\infty} x_j^i t^j$ for $x_j$ in the expression of $f$ gives a power series in $t$. The terms of the coefficient $\tilde{F}_i^\bullet$ of $t^i$ which are built up just by $x_1^i, 1 \leq j \leq m$, are precisely $\sum_{|\alpha|=i} f_\alpha x_\alpha^\bullet$, where $x_1 = (x_1^1, \ldots, x_1^m)$. Moreover, $F_i^\bullet = i! \tilde{F}_i^\bullet (x_i^j)$ and thus $f = \sum_{l=1}^{\infty} \frac{1}{l!} F_l^\bullet [1]$. 

**Example 12.** Consider the wt-homogenous ideal

$$I = (2b_1^2, 6b_1 b_2, 8b_1 b_3 + 6b_2^2 - 24a_3^3, \ldots).$$

From this we can deduce that if $I$ is the $D$-ideal of some polynomial $f$, then it will be $-u$ to degree $5 - \alpha$ of the form $f = y^2 - x^4$.

**Proposition 21.** As before we consider $k[q;m]$, $q \in N$, in a canonical way as a $k$-subalgebra of $k[[x_1^{\infty}]]$.

1. For any $F_0 \in k[0; m]$ its deg-order equals $\min\{l; F_l^\bullet \neq 0\}$.
2. If $(g) \subseteq (f)$, then $(Dg)^\bullet \subseteq (Df)^\bullet$.
3. $F_i^\bullet$ is wt-homogenous of weight $l$. $DF_i^\bullet$ is wt-homogenous of weight $l + 1$.

*Proof.* This is follows easily from Proposition 19.

**Remark.** Analogously to Proposition 18 one might ask the following question (Local Isomorphism Problem): Let $f : (X, x) \rightarrow (Y, y)$ be a morphism of formal germs. Assume that $f_m : (\pi_m^X)^{-1}(x) \cong (\pi_m^Y)^{-1}(y)$ for $m \gg 0$. Thus this imply that $f$ is already an isomorphism of formal germs? A positive answer was given by S. Ishii in the case that $(Y, y)$ is reduced, cf. [Ish]. Note that the coordinate ring of $(\pi_m^X)^{-1}(0)$ is precisely $J_m(X; 0)$.

### 3.2 The canonical form of the Derivation $D$

The objective in this section is to find a combinatorial description for the defining equations of the jet-schemes. For simplicity of notation we will restrict our considerations to hypersurfaces in $A^m$. If a hypersurface is given by a polynomial $f \in k[x_1, \ldots, x_m]$, then defining equations for its $q$th jet scheme are given by $D^i f \in k[q; m], 0 \leq i \leq q$, where $D$ is the $k$-derivation defined at the beginning of section 3.1, acting on the variables by $Dx_i^j = x_i^{j+1}$. We will write $\partial_i$,

3.2. THE CANONICAL FORM OF THE DERIVATION $D$

To denote the partial derivative $\frac{\partial}{\partial x_i}$ respectively $\partial_{i,x}$ for $\frac{\partial}{\partial x_i}$ (if the variable is clear out of context we simply write $\partial$). Moreover

$$k[q; m] = k[x_i^j; 1 \leq j \leq m, 0 \leq i \leq q],$$

is considered in the canonical way as a $k$-subalgebra of $k[[N]^m]$. We want to obtain a canonical form for $D|_{k[0,m]}$ (and its powers) in terms of the partial derivatives $\partial_{i,j}$.

**Example 13.** Write $x$ and $y$ instead of $x^1$ resp. $x^2$. Consider $f = x_0y_1^2 + x_0x_1y_0$ and its $D$-derivative

$$Df = x_1y_1^2 + 2x_0y_1y_2 + x_1^2y_0 + x_0y_1x_2 + x_0x_1y_1.$$ 

The same result can be obtained by applying the operator

$$T = x_1\partial_{0,x} + x_2\partial_{1,x} + y_1\partial_{0,y} + y_2\partial_{1,y}$$

to $f$.

For a set of variables $y_1, \ldots, y_N$ we denote by $W(y_1, \ldots, y_N)$ the Weyl-Algebra in indeterminates $y_1, \ldots, y_N$. It’s easy to see that for all $f \in k[q-1; m]$ the relation $Df = Tf$ holds, where $T$ is the operator

$$T = \sum_{j=1}^{m} \sum_{i=0}^{q-1} x_{i+1}^j \partial_{i,j} \in W(q; m) = W(x_i^j; 1 \leq j \leq m, 0 \leq i \leq q). \tag{3.2}$$

Indeed, both $D$ and $T$ define $k$-derivations on $k[[N]^m]$ which agree on the $x_i^j$. The generators of the $q$th jet ideal of the hypersurface $X$ defined by $f \in k[x_1, \ldots, x_m]$ are

$$F_i = D^i f, 0 \leq i \leq q,$$

where we naturally identify $f$ with $F_0 = f(x_1, \ldots, x_m) \in k[0;m]$. Recall that $D^2f$ is iteratively defined as $D(Df)$. Using (3.2) the element $D^2f$ can alternatively be obtained as follows: compute the composition of $T$ with itself in the Weyl-Algebra $W(q;m)$, and apply the resulting differential operator to $f$:

$$T^2 = \sum_{i,j} x_{i+1}^j \partial_{i,j} \circ \sum_{e,l} x_{e+1}^l \partial_{e,l} = \sum_{i,j,e,l} \left( \delta_{i,e+1} \delta_{j,l} x_{i+1}^j \partial_{e,l} + x_{i+1}^j x_{e+1}^l \partial_{i,j} \partial_{e,l} \right).$$

Applied to $f \in k[[N]^m]$ this gives exactly $D(D(f))$. For simplicity of notation we define $k$-derivations $D_q : k[q;m] \rightarrow k[q+1;m]$ by restriction of $D$ to $k[q;m]$:

$$D_q = D|_{k[q,m]} = \sum_{j=1}^{m} \sum_{i=0}^{q} x_{i+1}^j \partial_{i,j}.$$ 

Then $X_q$ is given by

$$F_0 = f(x_0^1, \ldots, x_0^m)$$

$$F_i = D^i F_0, 1 \leq i \leq q.$$
Example 14. We compute $D_{1}^{2}[k[0; m]] = D_{1}D_{0}$:

$$D_{1}D_{0} = (x_{1}\partial_{0} + x_{2}\partial_{1})(x_{1}\partial_{0}) = x_{1}\partial_{0}x_{1}\partial_{0} + x_{2}\partial_{1}x_{1}\partial_{0}$$

$$= x_{1}^{2}\partial_{0}^{2} + x_{2}\partial_{0} + x_{2}x_{1}\partial_{1}\partial_{0}$$

$$= x_{1}^{2}\partial_{0}^{2} + x_{2}\partial_{0}.$$  

The term $\partial_{1}\partial_{0}$ is identically zero on $k[0; m]$ since $\partial_{0}f \in k[0; m]$ for any $f \in k[0; m]$. This example suggests that there exists a canonical form of $D_{1}^{i}[k[0; m]]$ involving only partial derivatives $\partial_{0}$ and its powers.

**Proposition 22.** The operator $D_{1}^{i}[k[0; m]] = D_{i-1} \ldots D_{0}$ has a representation of the form:

$$D_{1}^{i}[k[0; m]] = \sum_{|\alpha| \leq i} d_{\alpha}^{i} \cdot \partial_{0}^{\alpha},$$

with $d_{\alpha}^{i} \in k[i; m]$, $\text{wt}(d_{\alpha}^{i}) = i$ and $\partial_{0}^{\alpha} = \prod_{j=1}^{m} \partial_{0,j}^{\alpha_{j}}, \alpha = (\alpha_{1}, \ldots, \alpha_{m}) \in \mathbb{N}_{0}^{m}$.

**Proof.** We prove this by induction on $i$, the case $i = 1$ being trivial. Assume that $D_{1}^{i-1}[k[0; m]] = \sum_{|\beta| \leq i-1} b_{\beta}\partial_{0}^{\beta}$ with coefficients $b_{\beta}$ of weight $i-1$. Composing $D_{1}^{i-1}[k[0; m]]$ with $D_{i-1} = \sum_{l} \sum_{e=0}^{i-1} x_{e+1}\partial_{e,l}$ gives ($E_{l}$ denotes the $l$th standard basis vector in $\mathbb{R}^{m}$)

$$D_{i-1}D_{i-1}^{i-1}[k[0; m]] = \sum_{e=0}^{i-1} \sum_{l=1}^{m} x_{e+1}^{l}\partial_{e,l} \circ \sum_{|\beta| \leq i-1} b_{\beta}\partial_{0}^{\beta}$$

$$= \sum_{e,l} \sum_{\beta} \left( x_{e+1}^{l}\partial_{e,l}(b_{\beta})\partial_{0}^{\beta} + x_{e+1}^{l}b_{\beta}\partial_{e,l}\partial_{0}^{\beta} \right)$$

$$= \sum_{\beta} \left( \sum_{e,l} x_{e+1}^{l}\partial_{e,l}(b_{\beta})\partial_{0}^{\beta} + \sum_{l} x_{e+1}^{l}b_{\beta}\partial_{0}^{\beta+1}E_{l} \right).$$

If $x_{e+1}^{l}\partial_{e,l}(b_{\beta}) \neq 0$ then it has weight $(e+1) + (i-1) - e = i$. Similar, if $x_{e+1}^{l}b_{\beta} \neq 0$ it has weight $1 + (i-1) = i$. Thus $D_{1}^{i}[k[0; m]]$ has the desired form.

**Corollary 23.** The coefficients $d_{\alpha}^{i} \in k[i; m]$ of the operator

$$D_{1}^{i}[k[0; m]] = \sum_{|\alpha| \leq i} d_{\alpha}^{i} \cdot \partial_{0}^{\alpha},$$

$i \geq 1$, in Proposition 22 fulfill the following recursion:

$$d_{\alpha}^{i} = \sum_{j=1}^{m} \left( \sum_{e=0}^{i-1} x_{e+1}^{j} \frac{\partial}{\partial x_{e}}(d_{\alpha}^{i-1}) + x_{e+1}^{j}(d_{\alpha}^{i-1} - E_{j}) \right) \quad (3.3)$$

with $E_{j}$ denoting the $j$th standard basis vector of $\mathbb{R}^{m}$.

**Proof.** This follows immediately from the proof of Proposition 22.
3.2. THE CANONICAL FORM OF THE DERIVATION $D$

Specialized to the case $m = 1$ the recurrence (3.3) becomes:

$$d_i^\alpha = \sum_{l=0}^{i-1} x_{i+1}^l \partial_l (d_{i-1}^{\alpha-1}) + x_1 d_{i-1}^{\alpha-1}. \quad (3.4)$$

Clearly, the $d_i^\alpha$ fulfill the following initial conditions:

$$d_i^\alpha = 0, \text{ for } \alpha \geq i + 1$$
$$d_i^\alpha = \delta_{i,\alpha}, \text{ for } i = 0 \text{ or } \alpha = 0. \quad (3.5)$$

Using this we compute the first powers of $D$:

$$D^1|_{k[0;1]} = x_1 \partial_0$$
$$D^2|_{k[0;1]} = x_2 \partial_0 + x_1^2 \partial_0^2$$
$$D^3|_{k[0;1]} = x_3 \partial_0 + 3x_1 x_2 \partial_0 + x_1^3 \partial_0^3$$
$$D^4|_{k[0;1]} = x_4 \partial_0 + (3x_2^2 + 4x_1 x_3) \partial_0^2 + 6x_1^2 x_2 \partial_0^3 + x_1^4 \partial_0^4.$$ 

**Corollary 24.** In case $m = 1$ we have for $i \geq 1$:

1. $d_1^i = x_i$
2. $d_i^i = x_i^2$
3. $d_{i+1}^{i+1} = \frac{i+1}{2} x_i^{i-1} x_2$

**Proof.** The first and second assertion are obvious from (3.4) and (3.5). The claim in 3. follows from the fact that $d_{i+1}^{i+1} = i x_i^{i-1} x_2 + x_1 d_{i-1}^i$. By this the coefficient $a_i$ of $x_i^{i-1} x_2$ fulfills the recursion $a_i = a_{i-1} + i, a_1 = 1$. 

We now give an explicit description of the coefficient polynomials $d_i^\alpha$. This was investigated in cooperation with Ch. Koutschan [Kou]. Especially the assertion of Proposition 25 was experimentally found by Ch. Koutschan.

Let $P(i, \alpha)$ denote the set of partitions of the integer $i$ into $\alpha$ parts $p_1, \ldots, p_\alpha$. For simplicity of language we will henceforth assume that $p_1 \leq p_2 \leq \cdots \leq p_\alpha$. Moreover we define a function $s = s(p)$ returning for each partition $p$ the number of ways to split a set of $p_1 + \cdots + p_\alpha$ elements into subsets of size given by the summands of the partition $p$. By $x_p$ we denote the monomial $x_{p_1} \cdots x_{p_\alpha}$. Then:

**Proposition 25.** With the above notation a solution to recurrence (3.4) is given by:

$$d_i^\alpha = \sum_{p \in P(i, \alpha)} s(p) \cdot x_p.$$

**Proof.** Set $g_i^\alpha = \sum_{p \in P(i, \alpha)} s(p) \cdot x_p$. We prove that $g_i^\alpha$ fulfills recurrence (3.4) and initial conditions (3.5). It’s easy to check that the initial conditions are satisfied. For example if $i = 0$, then for $\alpha \neq 0$ the set $P(0, \alpha) = \emptyset$. If $\alpha = 0,$
then \( P(0, \alpha) \) has one element, i.e., \( s(p) = 1 \). Substituting \( g'_\alpha \) for \( d'_\alpha \) in the right hand side of (3.4) yields

\[
\sum_{i=1}^{i-1} \sum_{p \in P(i-1, \alpha)} s(p)x_{i+1} \frac{\partial}{\partial x_i} \left( x_p \right) + \sum_{p \in P(i-1, \alpha-1)} s(p)x_1 \cdot x_p. \tag{3.6}
\]

Let us denote the first sum expression in (3.6) by \( \text{RHS}_1 \) and the second one by \( \text{RHS}_2 \). For \( q \in P(i, \alpha) \) the expression of \( g'_\alpha \) contains the term \( s(q)x_q \). We next determine the coefficient of \( x_q \) in (3.6).

Obviously, \( x_q \) appears in \( \text{RHS}_2 \) if and only if \( q_1 = 1 \). Then \( x_q \) has coefficient \( s(p^0) \), where \( p^0 \in P(i-1, \alpha-1) \) is the partition obtained from \( q \) by cancelling the first 1.

For the appearance of \( x_q \) in \( \text{RHS}_1 \) we write

\[
q = (1, \ldots, 1, 2, \ldots, 2, \ldots, i, \ldots, i),
\]

i.e., \( j_e \) is the number of \( e \) appearing in \( q \). Clearly, \( q \) is coming from those elements of \( P(i-1, \alpha) \) which have the form

\[
p^e = (1, \ldots, 1, e, \ldots, e, e + 1, \ldots, e + 1, \ldots, i, \ldots, i) \in P(i-1, \alpha)
\]

with coefficient \( (j_e + 1)s(p^e) \). In total the coefficient of \( x_q \) in (3.6) is

\[
s(p^0) + (j_1 + 1)s(p^1) + \ldots + (j_{i-1} + 1)s(p^{i-1}).
\]

The assertion follows with the next Lemma. \( \square \)

**Lemma 26.** For \( q \in P(i, \alpha) \) let \( j_e, p^e, e \in \{0, \ldots, i-1\} \) be defined as in the proof of Proposition 25. Then:

\[
s(q) = \sum_{e=0}^{i-1} (j_e + 1)s(p^e).
\]

**Proof.** For given \( q \in P(i, \alpha) \) the integer \( s(q) \) is the number of possibilities to decompose a set of \( i \) elements into subsets of size \( q_1, \ldots, q_\alpha \). Each such decomposition may be obtained from a decomposition of \( i - 1 \) into \( \alpha \) sets of size equal to \( q_1, \ldots, q_{e-1}, q_e - 1, q_{e+1}, \ldots, q_\alpha \), \( 1 \leq e \leq \alpha \). If the exceptional set is one of the first \( j_1 \) many, then one of these sets is empty, and there are \( s(p^0) \) many possibilities for this (note that for a partition the entries are ordered by increasing value!). If the exceptional set has \( e \neq 1 \) many elements, then we have \( (j_e + 1)s(p^e) \) many possibilities: there are \( j_e + 1 \) many possibilities where to put the “new” set of size \( e \). This gives in total \( \sum_{e=0}^{i-1} (j_e + 1)s(p^e) \), proving the lemma.

Alternatively one may proceed as follows: basic combinatorics shows that for a partition \( q \) as above the following holds:

\[
s(q) = \frac{1}{i! j_1 \ldots j_{i-1}} \cdot \binom{i}{j_1 \ldots j_{i-1}},
\]

\[
= \frac{1}{i! j_1 \ldots j_{i-1}} \cdot \frac{1}{i! j_1 \ldots j_{i-1}}.
\]
Next it’s easy to see that $s(p^e) = \frac{e+1}{i} \cdot \frac{j_{e+1}}{j_e+1} \cdot s(q)$ and thus

$$\sum_{e=0}^{i-1} (j_e + 1)s(p^e) = \sum_{e=0}^{i-1} \frac{j_{e+1}(e + 1)}{i} s(q) = \frac{1}{i} \left( \sum_{e=1}^{i} j_e \cdot e \right) s(q) = s(q),$$

which proves the lemma.

Remark. The polynomials $d^i_\alpha$ as in the last Proposition are known in the literature as the (exponential) partial Bell polynomials, see e.g. [Com74] or [Rio80]. This was pointed out to the author by G. Regensburger.

In literature the partial Bell polynomials are introduced by the relation

$$\frac{1}{\alpha!} \left( \sum_{e \geq 1} x^e e! \right)^\alpha = \sum_{i \geq 0} d^i_\alpha \frac{t^i}{i!},$$

$\alpha \in \mathbb{N}_0$. We will refer to the partial Bell polynomials as the univariate Bell polynomials. In analogy to the univariate case we define for $i \in \mathbb{N}$ and $\alpha = (\alpha_1, \ldots, \alpha_m) \in \mathbb{N}^m$ the multivariate partial Bell polynomial $d^i_\alpha$ by the relation

$$\frac{1}{\alpha_1!} \left( \sum_{e \geq 1} x^e e! \right)^{\alpha_1} \cdot \ldots \cdot \frac{1}{\alpha_m!} \left( \sum_{e \geq 1} x^m e! \right)^{\alpha_m} = \sum_{i \geq 0} d^i_\alpha \frac{t^i}{i!}. $$

Thus we may express the multivariate Bell polynomials in terms of univariate ones:

$$d^i_\alpha = \sum_{j_1, \ldots, j_m=1}^{i} \binom{i}{j_1 \ldots j_m} d^{\alpha_1}_{\alpha_1}(x^1) \cdots d^{\alpha_m}_{\alpha_m}(x^m). \quad (3.7)$$

Here we indicate the dependence of the polynomials on a particular subset of variables by adding an argument to the $d^i_\alpha$.

Proposition 27. The multivariate Bell polynomials fulfill recurrence (3.3).

Proof. During this proof we will abbreviate the multinomial coefficient

$$\binom{i}{j_1 \ldots j_m}$$

by $c_{i,j}$, $j = (j_1, \ldots, j_m)$. Moreover, in this context $d^i_\alpha$ will denote the product $d^{\alpha_1}_{\alpha_1} \cdots d^{\alpha_m}_{\alpha_m}$. Then substituting (3.7) into the RHS of equation (3.3) yields

$$\sum_{\gamma=1}^{m} \left( \sum_{e=0}^{x_{\gamma+1}} \frac{\partial}{\partial x_\gamma} \left( \sum_{|j|=i-1} c_{i-1,j} \cdot d^i_\alpha \right) + x_{\gamma} \sum_{|j|=i-1} c_{i-1,j} \cdot d^{i-E_\gamma}_{\alpha} \right)$$

which simplifies to
CHAPTER 3. JET AND ARC ALGEBRAS

\[
\sum_{\gamma=1}^{m} \sum_{|j|=i-1} c_{i-1,j} d_{\alpha_1}^{i_1} \cdots \left( \sum_{e=0}^{j} x_{e+1}^e \frac{\partial}{\partial x_e} (d_{\alpha_e}^{j_e}) + x_1^1 d_{\alpha_1,-1}^{j_1} \right) \cdots d_{\alpha_m}^{i_m}. \tag{3.8}
\]

Using recurrence (3.4) for the univariate Bell polynomials (3.8) then equals

\[
\sum_{\gamma=1}^{m} \sum_{|j|=i-1} c_{i-1,j} d_{\alpha_1}^{i_1} \cdots d_{\alpha_n}^{i_n} = \sum_{|j|=i} c_{i,j} d_{\alpha}^j
\]

which proves the Proposition.

As an immediate consequence of Proposition 22 we obtain the next proposition. It shows that the defining equations of the jet spaces are completely determined by the partial derivatives of generators of the ideal corresponding to the base scheme. This gives heuristic reasons why the local and global isomorphism problem “should” have a positive answer.

**Proposition 28.** Let \( f \in k[x] \) with \( q \)th jet algebra defined by \( F_0, \ldots, F_q \in k[q;m], q \in \mathbb{N} \cup \{\infty\} \). Then for all \( i \):

\[
F_i = \sum_{|\alpha| \leq i} d_{\alpha}^i \cdot \partial_0^\alpha f(x_1^1, \ldots, x_m^m),
\]

with \( d_{\alpha}^i \in k[i;m] \), \( \text{wt}(d_{\alpha}^i) = i \) the multivariate Bell polynomials, and \( \partial_0^\alpha = \prod_{j=1}^{m} \partial_{0,j}^{\alpha_j}, \alpha = (\alpha_1, \ldots, \alpha_m) \in \mathbb{N}_0^m \). Especially for the focussed jet algebras (at a closed point \( p \)):

\[
F_i^* = \sum_{|\alpha| \leq i} d_{\alpha}^i \cdot \partial_0^\alpha f(p).
\]

### 3.3 The regular locus of Jet Spaces

This section is devoted to the following question raised by M. Mustață in [Mus01] on local complete intersection (in short “l.c.i.”) varieties:

**Question 1** (Question 4.11 in [Mus01]). Let \( X \) be a l.c.i. variety with \( q \)th jet space \( X_q \), \( q \geq 1 \), and canonical projection \( \pi_q : X_q \to X \). Is the following assertion true?

\[
(X_q)_{\text{reg}} = \pi_q^{-1}(X_{\text{reg}}).
\]

In Proposition 4.12 of the same paper Mustață gives a positive answer for the case \( q = 1 \):

**Proposition** (Prop. 4.12 in [Mus01]). If \( X \) is a l.c.i. variety, then

\[
(X_1)_{\text{reg}} = \pi_1^{-1}(X_{\text{reg}}).
\]

We investigate some examples and give a positive answer for hypersurfaces \( X \) with pure-dimensional jet schemes.
Example 15. The assumption that $X$ is a variety – this implies in particular that $X$ is reduced – is vital for the Proposition. Consider $X = \text{Spec } k[x, y]/(x^2 y)$ with first jet-space given by

$$\begin{align*}
x_0^2 y_0 &= 0 \\
2x_0 y_0 x_1 + x_0^3 y_1 &= 0
\end{align*}$$

It has two components; $Y = \{x_0 = 0\}$ of codimension 1 and $Z = \{y_0 = y_1 = 0\}$ of codimension 2. The first component $Y$ is exactly $\pi_1^{-1}(X_{\text{sing}})$. Using the Jacobian criterion (see for example section 16.6 in [Eis95]) we see that $(X_1)_{\text{sing}} \subseteq (X_{\text{reg}})_{\text{sing}}$. This example essentially boils down to the next example:

Example 16. Consider for $n \geq 2$ the singular scheme $X(n) = \text{Spec } k[x]/(x^n)$ with first jet-scheme $X_1(n) = \text{Spec } k[x_0, x_1]/(x_0^n, x_0^{n-1} x_1)$.

It has one codimension 1 component, namely $\{x_0 = 0\}$. The Jacobian matrix $J$ of the defining equations for $X_1(n)$ is

$$J = \begin{pmatrix}
nx_0^{n-1} \\
(n-1)x_0^{n-2}x_1 \\
x_0^{n-1}
\end{pmatrix},$$

from which we see

$$(X_1(n))_{\text{sing}} = \begin{cases}
V(x_0, x_1) & \text{if } n = 2 \\
V(x_0) & \text{if } n > 3
\end{cases}.$$

So for $n = 2$ clearly $(X_1(n))_{\text{sing}} \subseteq \pi_1^{-1}(X_{\text{reg}})$, whereas the conjecture is true for $n > 3$.

Remark. In [Mus01] it is proven for any l.c.i. variety $X$ that if $X_q$ is irreducible for some $q \geq 1$, then $X_q$ is reduced. Is the converse true? This is Question 4.10 of [Mus01]. A solution for this problem would be given by a positive answer to Question 4. Indeed, assume that $X_q$ is reduced and reducible. Then any irreducible component in $\pi_q^{-1}(X_{\text{sing}})$ is generically smooth. But if $(X_q)_{\text{reg}} = \pi_q^{-1}(X_{\text{reg}})$ this gives a contradiction. The last proposition answers the problem for the case $q = 1$.

3.3.1 Hypersurfaces with pure-dimensional jet scheme

Let $X$ be a hypersurface in $k^n$ given by $f \in k[x_1, \ldots, x_m]$, $k$ a field of characteristic 0. Recall that the $q$-jet scheme $X_q$ of $X$ is given by the ideal $(F_0, \ldots, F_q) \subseteq k[q; m]$, where $F_0 = f(x_1^0, \ldots, x_m^0)$ and $F_i = DF_i$.

By Prop. 1.4 in [Mus01] it is known that the $q$th jet scheme of a l.c.i. variety $Y$ is pure dimensional if and only if $\dim Y_q \leq \dim Y \cdot (q + 1)$. In that case $Y_q$ is again a l.c.i. variety. In the case of the hypersurface $X$ this condition is:
dim \( X_q \leq (m-1) \cdot (q+1) \). If we assume that \( X_q \) is pure dimensional we may use the Jacobian criterion for regularity (see section 16.6 in [Eis95]) to determine the singular locus of \( X_q \), see Proposition 29.

Remark. Note that if \( Y \) is a l.c.i. variety and \( Y_{q+1} \) is pure-dimensional, so is \( Y_q, q \geq 1 \) (Proposition 1.6, [Mus01]). Especially, \( Y_q \) is pure-dimensional if it is irreducible, which is the case if and only if \( X \) has just canonical singularities. For more information on the relation between pure-dimensionality of \( Y_q \) and the question for log canonical singularities of \( Y \) see [Mus01], Thm. 3.4 and Prop. 3.6.

**Proposition 29.** Let \( X \subseteq \mathbb{A}^m \) be a hypersurface with pure dimensional \( q \)th jet scheme, \( q \geq 1 \), then

\[
(X_q)_{\text{reg}} = \pi_q^{-1}(X_{\text{reg}}).
\]

**Proof.** Since \( \pi_q : X_q \to X \) is a bundle over the regular part of \( X_q \) it’s clear that \( \dim X_q = (m-1) \cdot (q+1) \). Denote by \( F \) the column vector \((F_0, \ldots, F_q)^T\) and by \( \partial_{i,j} \) the partial derivative \( \partial_{i,j} \). Moreover set \( \partial F_0 \) for the row vector \((\partial_0, \ldots, \partial_{1,m})F_0 \). Applying the Jacobian Criterion for regularity we consider the \((q+1)\)-minors of \( \partial F \). Taking into account the special form of the \( F_i \) we see that \( \partial F \) is a \((q+1) \times m(q+1) \) matrix with entries in \( k[q;m] \) which has the shape

\[
\partial F = \begin{pmatrix}
\partial F_0 & 0 & \ldots & \ldots & 0 \\
* & \partial F_0 & 0 & \ldots & 0 \\
* & * & \ddots & \ldots & 0 \\
* & * & \ldots & \ldots & \partial F_0
\end{pmatrix}
\]

Let \( A = (A_{ij})_{i,j} \) be a \((q+1) \times (q+1) \) submatrix of \( \partial F \). The determinant of \( A \) is given by

\[
\det A = \sum_{\sigma \in S_{q+1}} \text{sgn}(\sigma) \prod_{i=0}^{q} A_{\sigma(i)}.
\]

It’s easy to see that each product of \( A_{ij} \) in the above sum contains exactly one factor stemming from the first row, which is either zero or \( \partial_{i,j}F_0 \) for some \( j \in \{1, \ldots, m\} \). Thus the ideal \( J \) of \((q+1)\)-minors of \( \partial F \) is contained in the ideal \((\partial_0, F_0, \ldots, \partial_{0,m}F_0) \) of \( F_0 \). Hence

\[
\pi_q^{-1}(X_{\text{sing}}) \subseteq (X_q)_{\text{sing}}.
\]

The reverse inclusion is trivial and we conclude that \( (X_q)_{\text{reg}} = \pi_q^{-1}(X_{\text{reg}}) \). \( \square \)

**Example 17.** Let \( f \in k[x_1, \ldots, x_m] \) define a hypersurface \( X \) in \( \mathbb{A}^m \), \( k \) algebraically closed. Assume that \( X \) has a singularity at \( p \in X \). Is it possible to find a second hypersurface \( Y \), given by \( g \in k[x_1, \ldots, x_m] \) such that \( p \in X \cap Y \) is a non-singular point? For generic \( Y \) we will have a complete intersection and its singular locus is given by \((f,g)\) and the 2-minors of

\[
\begin{pmatrix}
\partial_1f & \ldots & \partial mf \\
\partial_1g & \ldots & \partial mg
\end{pmatrix}
\]

which are of the form \( \partial_1f \partial_2g - \partial_1f \partial_2g \subseteq (\partial_1f, \ldots, \partial mf) \). Thus if \( p \) is the prime ideal corresponding to \( p \in X \cap Y \) we get – since \( I(X_{\text{sing}}) \subseteq p \) – that
3.3. THE REGULAR LOCUS OF JET SPACES

$I((X \cap Y)_{\text{sing}}) \subseteq \mathfrak{p}$.

Look at the example $f = y^2 - x^3 \in k[x, y, z]$, the cylinder over the Neil parabola. We choose as $Y$ the cylinder over $g = y + z^3$ which gives in the real picture below at the origin a smooth intersection:

![Image of the cylinder over the Neil parabola]

The previous computation shows that this is not the case over $\mathbb{C}$. Indeed, the minimal associated primes of $X \cap Y$ are given by $I_1 = (y + z^3, x - z^2)$ and $I_2 = (y + z^3, x^4 + xz^2 + x^2)$. The intersection is not (locally) irreducible at the origin, thus singular.

Remark. The last example gives an easy proof for $(X_1)_{\text{reg}} = (\pi_1)^{-1}(X_{\text{reg}})$ in the case of arbitrary hypersurfaces $X$ for which $X_1$ is a l.c.i. (this is a slightly stronger assumption than pure dimensionality). Indeed $X_1$ is given by $F_0$ and $F_1$, both defining hypersurfaces in $\mathbb{A}^{2m}$. The singular locus of $V(F_0)$ is a cylinder over $X_{\text{sing}}$. The intersection of $V(F_0)$ and $V(F_1)$ cannot be smooth at any point of $V(F_0)_{\text{sing}}$ as we saw above. Thus $\pi_1^{-1}(X_{\text{sing}}) = (X_1)_{\text{sing}}$.

3.3.2 Iterated Jet Schemes

Let $X$ be a variety and $X_1$ its space of 1-jets. We study the *iterated* $(1,1)$-jet space $X_{1,1}$ defined as

$$X_{1,1} = (X_1)_1.$$

Clearly, $X_{1,1}$ is again an affine scheme. If $X = \text{Spec } k[x_1, \ldots, x_m]/(f_1, \ldots, f_p)$ then we obtain the defining equations of $X_{1,1}$ as follows: every $f_j$ gives two defining equations $F_{0j}, F_{1j} = F_j^i \in k[1; m]$, each of which produces another two. For later calculations it is useful to see the precise structure: Substitute

$$(x_{00}^e + x_{01}^e \cdot s) + (x_{10}^e + x_{11}^e \cdot s) \cdot t$$

for $x_e$ in the expression of $f_j$. The coefficients of $1, s, t, st$ give the defining equations for $X_{1,1}$. These are (if some index in the argument of a polynomial is not specified, we assume that it depends on all variables with possible value for the index)

\[
\begin{align*}
F_{0j}^i &= f_j(x_{00}^i) \\
F_{01}^j &= \sum_{e=1}^m \partial_{x_e} f_j(x_{00}^e, \ldots, x_{01}^e) \cdot x_{01}^e = (f_j)_1(x_{00}^e, x_{01}^e) \\
F_{10}^j &= \sum_{e=1}^m \partial_{x_e} f_j(x_{10}^e, \ldots, x_{11}^e) \cdot x_{10}^e = (f_j)_1(x_{00}^e, x_{10}^e) \\
F_{11}^j &= D F_{01}^i, \text{ with } D x_{11}^i = x_{11}^i(l+1) \text{ for all } i, j, l.
\end{align*}
\]

Remark. Note that if $X \subseteq \mathbb{A}^m$ then $X_1 \subseteq \mathbb{A}^{2m}$, $X_2 \subseteq \mathbb{A}^{3m}$ and $X_{1,1} \subseteq \mathbb{A}^{4m}$. 

Analogously to the natural map $\pi^X_m : X_m \to X$ we introduce the map $\pi^X_{1,1} : X_{1,1} \to X$ given by the $k$-algebra homomorphism $(1 \leq e \leq m)$

$$k[x^e_{0i}]/(F^0_{il}, 1 \leq j \leq p) \to k[x^e_{0i}]/(F^0_{il}, 1 \leq j \leq p, 0 \leq i, l \leq 1).$$

Obviously, we have $\pi^X_{1,1} = \pi^X_1 \circ \pi^X_1$.

**Proposition 30.** Let $X \subset \mathbb{A}^m$ be an affine scheme. Then $X_2$ is a closed subscheme of $X_{1,1}$ and $\pi_2 = \pi_{1,1} \circ \theta$ where $\theta : X_2 \to X_{1,1}$ is induced by

$$\theta : k[x^e_{0i}; 0 \leq i, l \leq 1]/(F^0_{il}, 1 \leq j \leq p, 0 \leq i, l \leq 1) \to k[x^e_{0i}, x^e_{0j}]/(F^0_{il}, F^1_{il}, F^2_{il}),$$

with

$$x^e_{0i} \mapsto \begin{cases} x^0_{ij} & (i, l) = (0, 0) \\ x^1_{ij} & (i, l) \in \{(0, 1), (1, 0)\} \\ x^2_{ij} & (i, l) = (1, 1) \end{cases}.$$

**Proof.** By $(\ast)$ this $\theta$ is well defined. Obviously it defines an isomorphism between $X_2$ and

$$Y = \text{Spec} k[x^e_{0i}; e, i, l]/(F^0_{il}, \ldots, F^1_{il}, x^e_{01} - x^1_{01}; 1 \leq e \leq m).$$

The second claim is straight forward. $\square$

**Remark.** The bijection between $k$-points of $X_2$ and those of $Y$ is given by

$$X_2 \to Y : (x^0_{0i}, x^1_{0i}, x^2_{0i}) \mapsto (y^0_{0i}, y^1_{0i}, y^1_{1i}) = (x^0_{0i}, x^1_{0i}, x^1_{1i}),$$

$$Y \to X_2 : (y^0_{0i}, y^1_{0i}, y^1_{1i}) \mapsto (x^0_{0i}, y^1_{0i}, y^1_{1i}).$$

**Remark.** It is tempting to try to relate $(X_2)_{\text{sing}}$ to $(X_{1,1})_{\text{sing}}$, but be careful: If $X$ is a variety, then $X_1$ need not be a variety! Thus the question arises when

$$(X_{1,1})_{\text{sing}} \neq (\pi^X_1)^{-1}((\pi^X_1)^{-1}(X_{\text{sing}})).$$

**Example 18.** Let $X : xy = 0$, then $X_2$ is given by $x_0y_0, x_0y_1 + x_1y_0, 2x_1y_1 + x_0y_2 + x_2y_0$ with singular locus $(X_2)_{\text{sing}} : x_0, y_0, x_1y_1$. $X_2$ has four components

$$C_1 : \quad y_0 = y_1 = y_2 = 0$$

$$C_2 : \quad x_0 = y_0 = y_1 = 0$$

$$C_3 : \quad x_0 = y_0 = x_1 = 0$$

$$C_4 : \quad x_0 = x_1 = x_2 = 0.$$

The $(1, 1)$-jet scheme is given by $x_0y_0, x_0y_1 + x_0y_0, x_0y_2 + x_1y_1, x_0y_{10} + x_0y_{11} + x_1y_{10} + x_0y_{11} + x_{10}y_{11}$. Its singular locus is determined by

$$(X_{1,1})_{\text{sing}} : x_0, y_0, x_0y_1, x_0y_0, x_1y_1.$$

Note that in this example $(X_{1,1})_{\text{sing}} \cap X_2 = (X_2)_{\text{sing}}$ (where $X_2$ is identified with a closed subscheme of $X_{1,1}$ as in Proposition 30).

**Question 2.** Let $X$ be a variety. When does $(X_{1,1})_{\text{sing}} \cap X_2 = (X_2)_{\text{sing}}$ hold?
3.4 Hilbert-Poincare Series of Jet Algebras

The \( k \)-algebras \( J_q(\mathbb{A}^m_1) \), \( q \in \mathbb{N} \cup \{ \infty \} \), are graded with respect to the weight \( \text{wt}(x^i_j) = i \). Moreover, the defining equations of the jet space of a variety are weighted-homogenous. Thus it is natural to ask for the Hilbert-Poincare series \( \text{HP}_R(t) \) of a jet algebra \( R \) with respect to this weight. We restrict our considerations to hypersurfaces, in fact to irreducible hypersurfaces (especially reduced). Let \( f \in k[x] \) define a hypersurface \( X \) in \( \mathbb{A}^m \) and let \( F_0, \ldots, F_q \) be the induced homogenous defining equations of the \( q \)th jet space. The homogenous part of weight 0 is \( J_0(X) = k[0,m]/(F_0) \), which is not Artinian in general. Therefore we will consider the Hilbert-Poincare series, in short \( \text{HP} \)-series, of the focussed jet algebra

\[ J_q(X; p) = J_q(X) \otimes_{J_q(X)} \kappa(p) \]

of \( X \) in \( p \). Clearly, \( J_q(X; p) \) is the coordinate ring of the fibre of \( \pi_q^X : X_q \to X \) over \( p \). By Proposition [23] the image \( F_0^* \) of \( F_0 \) under the canonical map \( J_q(X) \to J_q(X; p) \) is still weighted homogenous. Since not all generators of the (focussed) jet algebras have in general weight 1 the Hilbert-function is not polynomial but quasi-polynomial. It is well known that in this situation the Hilbert-Poincare series is rational for each \( q < \infty \). If \( I \subseteq k[\mathbb{N}^m] \) is an ideal we will write \( I_q \) for its intersection with the subalgebra \( J_q(\mathbb{A}^m) \). Note:

**Lemma 31.** Let \( I \subseteq k[\mathbb{N}^m] \) be a (weighted) homogenous ideal. Then

\[ \text{HP}_{J_q(\mathbb{A}^m)/I}(t) = \lim_{q \to \infty} \text{HP}_{J_q(\mathbb{A}^m)/I_q}(t), \]

where the limit is taken with respect to the \( (t) \)-adic topology.

**Proof.** This is clear since \( J_q(\mathbb{A}^m)/I_i = [J_q(\mathbb{A}^m)/I_q]_i \) for \( i \leq q \) and the coefficient of \( t^i \) in \( \text{HP}_{J_q(\mathbb{A}^m)/I}(t) \) is exactly \( \dim_k [J_\infty(\mathbb{A}^m)/I_i]_i \).

**Example 19.** Consider \( R = J_\infty(\mathbb{A}^1; 0) = k[x; i \in \mathbb{N}] \). We compute its \( \text{HP} \)-series. The \( n \)th weighted piece \( R_n \) of \( R \) is generated by monomials of weight \( n \). A monomial \( x^\alpha = x_1^{\alpha_1} \ldots x_n^{\alpha_n} \) has weight

\[ \text{wt}(x^\alpha) = 1 \cdot \alpha_1 + \ldots + n \cdot \alpha_n. \]

The number of monomials of weight \( n \) is thus equal to the number of solutions in \( \mathbb{N}^n \) to the Diophantine equation \( \sum_{i=1}^n i \cdot \alpha_i = n \), which is the number \( p(n) \) of partitions of \( n \). Therefore, \( \text{HP}_R(t) = \sum p(n)t^n \) is the generating series of the partition function \( p(n) \) which is:

\[ \sum_{n=0}^\infty p(n)t^n = \frac{1}{\prod_{i \geq 1}(1-t^i)}. \]

Thus we see that for \( q \in \mathbb{N} \cup \{ \infty \} \) the \( \text{HP} \)-series of the \( q \)th jet algebra of \( \mathbb{A}^1 \) focussed at 0 is

\[ \text{HP}_{J_q(\mathbb{A}^1; 0)} = \mathbb{H}_q \]

with

\[ \mathbb{H}_q = \frac{1}{\prod_{1 \leq i \leq q}(1-t^i)}. \]

This especially shows that for \( q = \infty \) the \( \text{HP} \)-series is not rational.
Example 20. We will continue the last example and compute the HP-series for \( R = J_\omega(\mathbb{A}^2; 0) = k[x_i, y_i; i \in \mathbb{N}] \). Again we have to compute the number of monomials \( x^a y^b \) of given weight \( n \), which is the number of solutions in \( \mathbb{N}^n \times \mathbb{N}^n \) to the equation

\[
1 \cdot (\alpha_1 + \beta_1) + \ldots + n \cdot (\alpha_n + \beta_n) = n.
\]

For this we compute the number of monomials such that \( \text{wt}(x^a) = j \) and \( \text{wt}(x^b) = n - j \) which we have already computed as \( p(j) \) resp. \( p(n - j) \), and vary \( j \). Thus

\[
\dim_k R_n = \sum_{j=0}^{n} p(j)p(n - j).
\]

This is nothing but the \( n \)th coefficient of \( H^2 \) (resp. \( H^2_q \) for \( n \leq q \)), i.e., \( \text{HP}_{J_\omega(\mathbb{A}^2;0)} = H^2_q \). More generally we can conclude that \( \text{HP}_{J_\omega(\mathbb{A}^2;0)} = H^m_q \).

The result of the last example can also be deduced from the well-known fact (see e.g. [GP02], p. 276):

Lemma 32. Let \( A = \bigoplus_{a \geq 0} A_i \) be a graded \( k \)-algebra, \( M \) be a graded \( A \)-module and \( f \in A_d, d \in \mathbb{N} \). Then \( \ker(\cdot f) \) and \( \text{coker}(\cdot f) \) are graded \( A/(f) \)-modules with induced grading and

\[
\text{HP}_{M(t)}(1 - t^d) = \text{HP}_{\text{coker}(\cdot f)}(t) - t^d \cdot \text{HP}_{\ker(\cdot f)}(t).
\]

Indeed, the elements \( x_1^1, \ldots, x^m_1, x_1^2, \ldots, x^m_2 \) build a regular sequence in \( k[q;m] \).

Let \( S_{e,l} \) denote the algebra

\[
k[x_0^1, \ldots, x^m_0, \ldots, x_1^1, \ldots, x^m_1]/(x_0^1, \ldots, x^e_{l-1}).
\]

Then the kernel of \( (\cdot x_0^1) \): \( S_{e,l}(-\epsilon) \to S_{e,l} \) is trivial and one can conclude by induction that \( \text{HP}_{J_\omega(\mathbb{A}^2;0)}(t) = H^m_q \).

Proposition 33. Let \( X \subseteq \mathbb{A}^m \) be an irreducible hypersurface with jet algebra \( J_q(X) = J_q(\mathbb{A}^m; I_q) \), where \( I = (F_0, F_1, \ldots) \) as introduced before. Then if \( p \) is the generic point of \( X \):

\[
\text{HP}_{J_q(\mathbb{A}^m;p)}(t) = H^m_q^{-1}.
\]

Proof. Set \( L = \text{Quot}(k[0;m]/(F_0)) \). We will show that \( F_1^*, \ldots, F_q^* \) define a regular sequence in \( J_q(\mathbb{A}^m;p) \). Indeed, \( (F_1^*, \ldots, F_m^*) \neq (1) \). It remains to show that for all \( i \in \{2, \ldots, q\} \) the element \( F_i^* \) is a non-zerodivisor in

\[
J_q(\mathbb{A}^m;p)/(F_1^*, \ldots, F_{i-1}^*).
\]

For this reason we write \( F_i^* = c_1 x_1^i + \cdots + c_m x^i_m + d \) with \( c_i \in L \) and

\[
d \in L[x_1^i; 1 \leq j \leq m, 1 \leq e \leq i - 1].
\]

At least one \( c_i \) does not vanish, w.l.o.g. this is \( c_1 \). Consider the following homogenous \( k \)-algebra homomorphism:

\[
\varphi: x_0^1 \mapsto \begin{cases} x_0^1 \\ \frac{1}{c_1}(x_1^i - \sum_{l=2}^m c_l x_1^l - d) \end{cases} \quad \begin{cases} (e,j) \neq (i,1) \\ (e,j) = (i,1). \end{cases}
\]
This coordinate change transforms $F_i$ into $x_i^1$, which is clearly a non-zero divisor in $J_q(k^m; p)/(F_i^1, ..., F_i^{i-1})$. Now using the above Lemma finishes the proof of the Proposition.

**Corollary 34.** With the notation of the previous Proposition let $p \in X$ be an arbitrary smooth point. Then:

$$\text{HP}_{J_q(k^m; p)}(t) = \mathbb{H}^{m-1}_q.$$ 

### 3.5 Completions of Polynomial Rings

This section starts the study of completions of polynomial rings in countably many indeterminates over a field $k$ of characteristic 0. In the Noetherian situation (i.e., for polynomial rings in finitely many variables) completions are a powerful tool to study local properties of a variety. Its usefulness is based on flatness of the completion over the given local ring: If $I = (f_1, ..., f_n)$ is an ideal in a Noetherian local ring $R$, then its closure in the completion $\widehat{R}$ is generated again by $f_1, ..., f_n$. Thus the completion of a quotient can be described easily. In the non-Noetherian setting flatness does not hold in general. Completions of such kind have been investigated by Reguera in [Reg06] and [Reg09]. There it is shown that if $z$ is the generic point of an irreducible generically stable subset of $X_\infty$, some variety, then $\widehat{O}_\infty, z$ is Noetherian (Cor. 4.6, [Reg06]). More explicit results can be found in [Reg09]. In the following we compute the completion of $k[[n^n]]_p$, $p \in \mathbb{A}_\infty^n$, in some simple cases.

**Example 21.** Consider the polynomial ring $k[[n^n]] = k[x] = k[x_1, ..., x_n]$, $n \in \mathbb{N}$. Denote the (maximal) ideal $(x_1, ..., x_n)$ by $m$ and endow $k[x]$ with the $m$-adic topology, i.e., the topology induced by the filtration

$$k[x] \supseteq m \supseteq m^2 \supseteq \ldots.$$

Completion with respect to this topology is another way to obtain the ring of formal power series in $n$ variables (compare section 1.4.1):

$$\lim_i k[x_1, ..., x_n]/m^i = k[[x_1, ..., x_n]].$$

Indeed, the following map defines an isomorphism of $k$-algebras:

$$\theta: k[[x]] \to \prod_{i \geq 1} k[x]/m^i \to \lim_i k[x]/m^i; \xi \mapsto (\xi + m^i),$$

with $m$ denoting the maximal ideal in $k[[x]]$. Its inverse is given by

$$\psi: (\xi_i) \mapsto \sum_{i \geq 0} (\xi_{i+1} - \xi_i),$$

where the $\xi_i$ are representatives of $\bar{\xi}_i$ and $\xi_0$ is set to 0. Note that $\psi(\xi)$ is independent of the chosen representatives (since defined by a telescoping sum). Moreover, by coherence of the sequence $\xi$ we have $\xi_{i+1} - \xi_i \in m^i$, thus the sum in the definition of $\psi$ converges in the $m$-adic topology. Therefore $\psi$ is well-defined. A short computation shows that both $\theta$ and $\psi$ are $k$-algebra homomorphisms:
It’s clear that $\psi$ is $k$-linear. For the ring homomorphism property note that for $i \leq j$ the $i$th homogenous part of $\psi(\xi)$ is given by the degree $i$ part $\xi_{i+1}$ of a representative $\xi_{j+1}$. But then

$$
(\psi(\xi \eta))^i = \psi((\xi \eta)_i)^i = (\xi_{j+1} \eta_{j+1})^i
$$

The last term being

$$
\sum_{a+b=i} \xi_{j+1}^a \eta_{j+1}^b = (\psi((\xi)) \psi((\eta)))^i.
$$

For every $f \in k[\mathbb{N}]$ we define its degree $\deg f$ as

$$
\deg f = \max\{|\alpha|; \alpha \in \text{supp}(f)|\}.
$$

If $f = 0$, then we set $\deg f = \infty$. Analogously, we define the order of an element $f \in k[\mathbb{N}]$ as the minimum of all $|\alpha|$, $\alpha \in \text{supp}(f)$, respectively $\infty$ in case of $f = 0$. Note: for simplicity of notation we write $k[\mathbb{N}]$ instead of $k[\mathbb{N}_0]$. Consider for every $n \in \mathbb{N}$ the set of exponents of monomials in $k[\mathbb{N}]$ of the same degree $n$, i.e.,

$$
M_n = \{\alpha \in \mathbb{N}; |\alpha| = n\}.
$$

In contrast to the last example the completion of $k[\mathbb{N}]$ with respect to $m = (x_0, x_1, \ldots)$ is not the power series ring $k[\mathbb{N}]$ in variables $x_i$, $i \in \mathbb{N}_0$, which would contain elements like $\sum_{i=0}^{\infty} x_i$. We define the degree-finite power series

$$
k[[\mathbb{N}]]_{\text{fin}} = \{f \in k[[\mathbb{N}]]; |\text{supp}(f) \cap M_n| < \infty, \text{ for all } n \in \mathbb{N}\}.
$$

We denote by $m_1$ the closure of $m = (x_0, x_1, \ldots)$ in $k[[\mathbb{N}]]_{\text{fin}}$. It is given by the ideal of degree-finite power series in variables $x_i$, $i \in \mathbb{N}$ without constant term. More generally we consider

$$
m_i = \{f \in k[[\mathbb{N}]]_{\text{fin}}; \text{ord } f \geq i\}.
$$

**Proposition 35.** Let $\{k[\mathbb{N}]/m^i, \pi^i_j\}$ be the projective system given by the canonical maps

$$
\pi^i_j: k[\mathbb{N}]/m^i \leftarrow k[\mathbb{N}]/m^j
$$

for $j \geq i$. Then:

$$
\lim_{\leftarrow i} k[\mathbb{N}]/m^i \cong k[[\mathbb{N}]]_{\text{fin}}.
$$

**Proof.** Analogously to Example 21 we consider the map

$$
\psi: \lim_{\leftarrow i} k[\mathbb{N}]/m^i \rightarrow k[[\mathbb{N}]]_{\text{fin}}; \xi = (\xi_i)_i \mapsto \sum_{i \geq 0} (\xi_{i+1} - \xi_i)
$$

with $\xi_0 = 0$. By the same reasoning as in the example $\psi$ is well-defined. Moreover, $\text{im}(\psi) \subseteq k[[\mathbb{N}]]_{\text{fin}}$, since $\text{ord } \xi_{i+1} - \xi_i \geq i$, i.e., just finitely many terms of given order appear in $\psi(\xi)$.

Obviously

$$
k[[\mathbb{N}]]_{\text{fin}}/m_1 \cong k[[\mathbb{N}]]/m^1.
$$

Therefore we get a surjective map
3.5. COMPLETIONS OF POLYNOMIAL RINGS

\[ \theta : k[\mathbb{N}]_0 \to \varprojlim_{i} k[\mathbb{N}]/m^i; f \mapsto (f + m_i), \]

with \( \psi \theta = \text{id} \) and \( \theta \psi = \text{id} \). Both maps are \( k \)-algebra homomorphisms. \( \square \)

Remark. Consider \( k[\mathbb{N}] \) with the linear topology defined by \( m^i, i \in \mathbb{N} \). This topology is Hausdorff, i.e.,

\[ \bigcap_{i \in \mathbb{N}} m^i = \{0\}. \]

Indeed, by definition \( f \in m^i \) if and only if \( \text{ord } f \geq i \). Thus, \( f \in \bigcap_{i \in \mathbb{N}} m^i \) implies \( \text{ord } f \geq i \) for all \( i \in \mathbb{N} \), i.e., \( f = 0 \), and the assertion follows. From this we conclude that the canonical map \( k[\mathbb{N}] \to k[\mathbb{N}]_0 \) is injective (see [Mat89]).

Remark. Let \( f \in k[[\mathbb{N}]]_0 \) and \( \{x_j; j \in J\} \) be a set of variables. Then we may expand \( f \) as a power series in the \( x_j, j \in J \) with coefficients which are power series in the remaining indeterminates \( x_j, j \in J' = \mathbb{N}_0 \setminus J \). In that case we will use the following notation:

\[ f = \sum_{\alpha \in \mathbb{N}^{(J)}} f_\alpha x^\alpha. \]

If \( J = \{0, \ldots, d\} \) we simply write \( f = \sum_{\alpha \in \mathbb{N}^{d+1}} f_\alpha x^\alpha, f_\alpha \in k[[x_j; j \in J']] \).

**Proposition 36.** For \( d \in \mathbb{N}_0 \) consider the ideal \( n = (x_0, \ldots, x_d) \subseteq k[\mathbb{N}], J = \{0, \ldots, d\}, \) and set \( p = (x_j; j \in J') \). Let \( \{k[\mathbb{N}]/n^i, \pi^i\} \) be the canonical projective system, then:

1. \( \varprojlim_{i} k[\mathbb{N}]/n^i = k[x_{d+1}, \ldots][x_0, \ldots, x_d] \).
2. For any \( i \in \mathbb{N} \) the ideal

\[ p_i = \{f = \sum_{\alpha \in \mathbb{N}^{d+1}} f_\alpha x^\alpha \in k[x_{d+1}, \ldots][x_0, \ldots, x_d]; f_\alpha \in (x_j, j \in J')^i\} \]

is the closure of the ideal \( p^i \) in \( k[x_j; j \in J'][x_0, \ldots, x_d] \) with respect to the topology given by \( n_j = \ker(p_j) \), where

\[ p_e : K[x_j; j \in J'][x_0, \ldots, x_d] \to k[\mathbb{N}]/n^e \]

is the natural projection.

Remark. More explicitly the ideals \( n_e \) are of the form

\[ n_e = \{f \in k[x_j; j \in J'][x_0, \ldots, x_d]; \text{ord}_{(x_0, \ldots, x_d)} f \geq e\}. \]

**Proof.** Ad 1. The first result can be proved in exactly the same way as the last Proposition. Nevertheless we will vary the proof a bit: Write every element \( f \in R = k[x_j; j \in J'][x_0, \ldots, x_d] \) as

\[ f = \sum_{\alpha \in \mathbb{N}^{d+1}} f_\alpha x^\alpha \]
with \( f_\alpha \in k[x_j; j \in J'] \) and \( x^\alpha = x_0^\alpha \cdots x_d^\alpha \). The homogenous part \( f^{(i)} \) of degree \( i \) of \( f \) is then
\[
\left( \sum_{|\alpha| \leq i} f_\alpha x^\alpha \right)^{(i)},
\]
hence \( R \subseteq k[[N]]_{\text{fin}} \). Consider
\[
\theta : \lim_{i \to \infty} k[[N]]/n^i \to k[[N]]_{\text{fin}}; (\xi_i) \mapsto \sum (\xi_{i+1} - \xi_i)
\]
with \( \xi_0 = 0 \). As before one can see that \( \theta \) is a well-defined homomorphism of \( k \)-algebras. Moreover, \( R \subseteq \text{im}(\theta) \) since for any \( f \in R \) we have
\[
f = \theta((f \mod n_i)_i)
\]
using the natural identification
\[
R/n_i \cong k[[N]]/n^i.
\]
Clearly, \( \theta \) is injective: \( \theta(\xi) = 0 \) if and only if all homogenous parts of degree \( j \in \mathbb{N} \) are zero. But
\[
\theta(\xi)^{(j)} = (\xi_j)^{(j)}
\]
for \( j < i \). Thus \((\xi_i)_i = (0)\). It remains to show that \( \text{im}(\theta) \subseteq R \), but this is clear from the above statements.

Ad 2. The closure \( \overline{p^i} \) of \( p^i \) with respect to the topology defined by the filtration \( n_1 \supseteq n_2 \supseteq \cdots \) is given by
\[
\overline{p^i} = \bigcap_{j \in \mathbb{N}} (p^i + n_j).
\]
We first show that \( p_i \subseteq \overline{p^i} \): Let \( f = \sum f_\alpha x^\alpha \) be an element of \( p_i \). Then for all \( \alpha \in \mathbb{N}^{i+1} \) the corresponding coefficient \( f_\alpha \) lies in \( p^i \), and for all \( j \in \mathbb{N} \) we can write \( f \) as
\[
f = f'_j + j''_j,
\]
with \( f'_j = \sum_{|\alpha| < j} f_\alpha x^\alpha \) and \( j''_j = \sum_{|\alpha| \geq j} f_\alpha x^\alpha \). Since all \( f_\alpha \in p^i \) the polynomial \( f'_j \) lies in \( p^i \). By construction \( j''_j \in n_j \). Therefore \( f \in \overline{p^i} \).

For the reverse inclusion \( p_i \supseteq \overline{p^i} \) assume that there exists an \( f \in \overline{p^i} \) which does not lie in \( p_i \). As we have already shown that \( p_i \subseteq \overline{p^i} \), we may assume without loss of generality that \( f = f_\alpha x^\alpha \) with \( \deg_{\alpha \in J} f_\alpha < i \). Moreover, since \( f \in \overline{p^i} \) for every integer \( j \geq 1 \) we have \( f \in p^i + n_j \). So we see that no term of \( f \) belongs to \( p^i \), thus \( f \in \bigcap_j n_j \) and \( f = 0 \).

\[
\square
\]

Remark. With the notation from above we conjecture that \( p_i \neq p^i_1 \). A possible counterexample is given in \( R = k[x_1, x_2, \ldots] [[y]] \) by
\[
f = \sum_{i \geq 1} x_i^2 \cdot x_{i-1} = x_1^2 + x_2^2 y + x_3^2 y^2 + \ldots \in m_2.
\]
3.5. COMPLETIONS OF POLYNOMIAL RINGS

Proposition 37. With the notation introduced above there exists an isomorphism

\[ k[x_{d+1}, \ldots][x_0, \ldots, x_d]/\mathfrak{p}_i \cong k[x_{d+1}, \ldots]/\mathfrak{p}^i[x_0, \ldots, x_d], \]

inducing an isomorphism of the corresponding inverse systems. Moreover

\[ \lim_{i \to j} \left( \lim_{n \to j} \frac{k[\mathbb{N}]/\mathfrak{m}_i}{\mathfrak{m}_i} \right) \cong k[\mathbb{N}]_{\text{fin}}. \]

Proof. For the first assertion consider the map

\[ \varphi: k[x_j; j \in J'][x_0, \ldots, x_d] \to k[x_j; j \in J']/\mathfrak{p}^i[x_0, \ldots, x_d] \]

given by \( f = \sum_{\alpha \in \mathbb{N}^{d+1}} f_{\alpha} x^\alpha \mapsto \sum_{\alpha} f_{\alpha} x^\alpha. \) It is obviously a well-defined surjective \( k \)-algebra homomorphism. Moreover,

\[ \varphi(f) = 0 \iff f_{\alpha} = 0 \text{ for all } \alpha \iff f_{\alpha} \in \mathfrak{p}^i \text{ for all } \alpha \iff f \in \mathfrak{p}_i. \]

The last claim is proven as follows. By the first assertion and Proposition 36 1, it is enough to show that there exists an isomorphism

\[ \lim_{i \to j} (k[x_j; j \in J']/(x_j; j \in J')^{i}|[x_0, \ldots, x_d]) \to k[\mathbb{N}]_{\text{fin}}. \]

We define such a \( \theta \) by

\[ \theta(\xi) = \sum_{i \geq 0} (\xi_{i+1} - \xi_i), \]

where again \( \xi_0 = 0. \) Clearly, \( \theta \) is well-defined: it is independent of the chosen representatives \( \xi_i \) and \( \text{im}(\theta) \subseteq k[\mathbb{N}]_{\text{fin}}. \) Moreover, \( \theta \) is surjective: let \( f = \sum_{\alpha \in \mathbb{N}^{d+1}} f_{\alpha} x^\alpha, \ f_{\alpha} \in (x_j; j \in J'), \) be an element of \( k[\mathbb{N}]_{\text{fin}}. \) Consider \( \xi_i = \sum f_{\alpha} x^\alpha \) where \( \alpha = \alpha_i' + \alpha_i'' \) with \( \text{deg}_{x_j; j \in J'} f_{\alpha'} < i \) and \( \text{ord}_{x_j; j \in J'} f_{\alpha''} \geq i. \) The sequence \( \xi = (\xi_i) \) is coherent, and clearly \( \theta(\xi) = f. \) Injectivity of \( \theta \) follows from the fact that if \( \theta(\xi) = \theta(\eta), \) then \( \xi_j^{(j)} = \eta_j^{(j)} \) for all \( j < i, \) since \( \theta(\xi_j^{(j)}) = \xi_i^{(j)}. \)

Let \( I \) be an ideal in \( k[\mathbb{N}]. \) We are interested in the completion of the quotient \( k[\mathbb{N}]/I \) with respect to the filtration induced by \( (\mathfrak{m}')_{i \in \mathbb{N}}. \) Since the inverse system \( \{k[\mathbb{N}]/\mathfrak{m}_i, \pi_i^j\} \) is surjective, i.e., all the \( \pi_i^j \) are surjective, the exact sequence

\[ 0 \to I \to k[\mathbb{N}] \to k[\mathbb{N}]/I \to 0 \]

induces an exact sequence

\[ 0 \to \lim_{i \to j} I/(I \cap \mathfrak{m}^i) \to k[\mathbb{N}]_{\text{fin}} \to \lim_{i \to j} (k[\mathbb{N}]/I)/\mathfrak{m}^i \to 0, \]

see for example [Har77], II.9. In what follows we will as usual abbreviate the projective limit by "\( \sim \)." For example we will write \( \hat{I} \) instead of \( \lim_{i \to j} I/(I \cap \mathfrak{m}^i). \) Thus, the above exact sequence reads as

\[ k[\mathbb{N}]/I = k[\mathbb{N}]_{\text{fin}}/\hat{I}. \]

In order to work with this object it would be advantageous to know an explicit description of \( \hat{I}. \) Recall the finite dimensional situation, i.e, the case of an ideal \( I \) in a Noetherian ring \( R. \) Completion w.r.t. some ideal \( J \subseteq R \) induces
\( \hat{R}/I \cong \hat{R}/\hat{I} \). Since \( \hat{R} \) is a flat \( R \)-module we know that if \( f_1, \ldots, f_n \) are generators for \( I \) in \( R \) then they are generators for \( \hat{I} \) in \( \hat{R} \).

There are two immediate possibilities to compute \( \hat{I} \). Either \( \hat{I} \) can be seen as \( \lim I/(I \cap m^i) \) or as the closure of \( \operatorname{inj}(I) \), the image of \( I \) under the canonical map \( k[[N]] \to \hat{k[[N]]} \). The closure can be computed as the intersection

\[
\overline{\operatorname{inj}(I)} = \cap_{j \in \mathbb{N}} (\operatorname{inj}(I) + m_i).
\]

Here \( m_i \) is the kernel of the canonical map \( p_i : k[[N]]_{\text{fin}} \to k[[N]]/m_i \).

**Example 22.** Consider \( I = (x_0) \subseteq k[[N]] \). Then \( I \cap m^i = (x_0^i, x_0^{i-1}x_1, \ldots) \), the generators being monomials of degree \( i \) with \( x_0 \) appearing in non-zero power. So \( I/(I \cap m^i) \) consists of multiples of \( x_0 \) which have degree less than \( i \). Hence we conclude that

\[
\hat{I} = \{ f \in k[[N]]_{\text{fin}}; x_0f \} = k[[N]]_{\text{fin}}(x_0).
\]

Indeed, denoting the right-hand side of equation (3.9) by \( A \), it is obvious that \( A \subseteq \overline{\operatorname{inj}(I)} \). To see the reverse inclusion assume that there exists an \( f \in \overline{\operatorname{inj}(I)} \) such that \( x_0 \nmid x^\alpha \) for some \( \alpha \in \operatorname{supp}(f) \). In fact we may assume that this holds for all \( \alpha \in \operatorname{supp}(f) \). But then no term in \( f \) lies in \( \operatorname{inj}(I) \), i.e., \( f \in \cap_{0 \leq m} m \), which is 0.

**Example 23.** Let \( f = x - y \in k[x, y] \). The induced felt (see chapter 1 and section 1.4.2) is given by the ideal \( I = (x_0 - y_0, x_1 - y_1, \ldots) \). Since the \( x_i - y_i \) are homogenous we see that \( I \cap m^i \) can be identified with (see Proposition 38 below)

\[
\{ g \in k[[N]]; g = \sum_{j \in J} \alpha_j (x_j - y_j), |J| < \infty, \operatorname{ord} \alpha_j \geq i - 1 \}.
\]

More generally we have:

**Proposition 38.** Let \( f \in k[x_1, \ldots, x_m] \) be homogenous of degree \( d \). Then for \( I = (F_0, F_1, \ldots) \):

\[
I \cap m^i = m^{i-d} \cdot I.
\]

**Proof.** Since \( f \) is homogenous of degree \( d \) so are all \( F_i \). Any element \( g \in I \cap m^i \) is of the form

\[
g = \sum_{j \in J} \alpha_j F_j,
\]

with \( |J| < \infty \) and \( \alpha_j \in k[[N]]^{\text{mn}} \). Set \( e = \min \{ \operatorname{ord} \alpha_j \} \); we may assume that

\[
e = \min \{ l \in \mathbb{N}; \sum \alpha_j^{(l)} f_j \neq 0 \}.
\]

Under these assumptions: \( g \in I \cap m^i \iff e \geq i - d \). Hence \( I \cap m^i = m^{i-d} \cdot I. \)

**Remark.** We conjecture for the general case: For an arbitrary ideal

\[
I = (f_0, f_1, \ldots)
\]

the closure \( \hat{I} \) equals the ideal \( I_{\text{fin}} / \sum_{i=0}^{\infty} \alpha_i f_i \in k[[N]]_{\text{fin}} \) with \( \alpha_i \in k[[N]]_{\text{fin}} \). Up to now we cannot even answer the question: Is every ideal in \( k[[N]]_{\text{fin}} \) generated by countably many elements?
Remark. In this remark we collect further interesting questions concerning the algebraic structure of $k[[\mathbb{N}]]_{\text{fin}}$. First: Is $k[[\mathbb{N}]]_{\text{fin}}$ a unique factorization domain? It is well-known that every polynomial ring in finitely many variables over a field is UFD. Using the Weierstrass Preparation Theorem one concludes that also formal (resp. convergent) power series rings in finitely many variables are UFD’s. We ask whether the analog holds for $k[\mathbb{N}]$ respectively $k[[\mathbb{N}]]_{\text{fin}}$? Clearly we have:

Proposition. $k[\mathbb{N}]$ is a unique factorization domain.

Proof. Let $f \in k[\mathbb{N}]$, then $f \in R_N = k[x_i; 0 \leq i \leq N]$ for some $N \in \mathbb{N}$. Since $R_N$ is a UFD $f$ has in $R_N$ a unique factorization into irreducible elements $f = f_1 \cdots f_p$. If there would be another set of irreducible polynomials $f'_1, \ldots, f'_q \in k[\mathbb{N}]$, $q \in \mathbb{N}$, with $f = f'_1 \cdots f'_q$, then all $f'_i$ would be contained in an $R_{\hat{N}}$, w.l.o.g. $\hat{N} \geq N$. But then since $R_N \subseteq R_{\hat{N}}$, and $R_{\hat{N}}$ is UFD, we see that $q = p$ and \{ for $1 \leq i \leq p$ \} = \{ for $1 \leq i \leq q$ \}. We conclude that $k[\mathbb{N}]$ is a UFD. 

It is not clear how to relate the UFD property of $k[\mathbb{N}]$ with $k[[\mathbb{N}]]_{\text{fin}}$. The way in the classical, i.e., finite dimensional, setting is via the Weierstrass Preparation Theorem. More precisely $f \in k[[x_1, \ldots, x_n]]$ is written (after a linear change of coordinates) as an element in $k[[x_1, \ldots, x_{n-1}][x_n]]$. Using induction and the Gauss Lemma one concludes that $k[[x_1, \ldots, x_n]]$ is a UFD.

However, in the setting of power series rings in infinitely many variables it is not clear how to generalize $x_n$-regularity and the Weierstrass Theorem. Even if that is done the induction argument will be more involved than in the finite dimensional case. Since the Weierstrass Theorem is vital to a large number of results in singularity theory on might wonder for an appropriate substitute in the present setting: What is a substitute for the Weierstrass Preparation Theorem in $k[[\mathbb{N}]]_{\text{fin}}$?
Chapter 4

Constructions with Étale Neighbourhoods

A basic but powerful tool in analysis and differential geometry is the inverse function theorem, which asserts that if the tangent map at a point is an isomorphism, so is the original map, at least in a sufficiently small neighbourhood of the point. Exactly the invertibility in a “small neighbourhood” causes troubles in algebraic geometry. If one works over the real or complex numbers the Euclidean topology is fine enough to offer sufficiently small neighbourhoods. This is not any longer the case for arbitrary fields, where the notion of “Euclidean topology” is not defined. The Zariski topology on the other hand is much too coarse to allow an inverse function theorem, see example 25 below. The notion of étale neighbourhood is a profitable tool to exploit morphisms which “would fulfill the assumptions of the inverse mapping theorem if considered over C”.

A short introduction to étale morphisms is given in section 4.1. For a detailed introduction we refer to the literature, e.g. [Har77], [KPR75] or [Mil80]. The most used properties of étale morphisms in the present chapter are openness and the fact that they induce isomorphisms of the completions of the respective local rings.

The key problem is the following: Let $X$ be a variety over an algebraically closed field $k$ and $x \in X$ a point. Denote the completion of the local ring of $X$ at $x$ by $\hat{O}_{X,x}$. Let $P$ be a property of $\hat{O}_{X,x}$. What information can be gained on the set $X_P$ of all $x \in X$ such that $\hat{O}_{X,x}$ has property $P$? Such properties of the completion are for instance: being an integral domain, reduced, a principal ideal domain or being normal crossings. We especially prove that the normal crossings locus $X_{nc}$ is open in $X$, a hypersurface in some $\mathbb{A}^n$ (a generalization to arbitrary varieties is straight forward). This result is well-known to experts in resolution of singularities, but up to the knowledge of the author there is no reference for this question in the above general setting. Note, that it is quite easy to prove this fact if a Euclidean topology (and thus a notion of analytic maps) is available. In fact, one could see étale neighbourhoods as a substitute for the respective method of proof.

The structure of the proof for the normal crossings case is as follows: First prove
a “global” version of the assertion, i.e., show that for a union of hypersurfaces
the set of points where it is algebraic normal crossings (also known as simple
normal crossings in the literature) is open, see Proposition 4.1. Next translate
the formal property of being normal crossings into the global property of being
algebraic normal crossings. This uses étale neighbourhoods and the powerful
Artin Approximation Theorem [Art69]. In a last step openness of the algebraic
normal crossings locus in the étale neighbourhood is transferred to the original
variety by openness of étale morphisms.

This chapter was developed in joint work with Dominique Wagner and will be
part of a forthcoming survey paper on basic constructions using étale neigh-
bourhoods.

4.1 Étale and Formal Neighbourhoods

Let \( k \) be an algebraically closed field of arbitrary characteristic. Denote by \( k[x] \)
the polynomial ring in the variables \( x = (x_1, \ldots, x_n) \) over \( k \). Its completion
w.r.t. the maximal ideal \( (x) \) is the ring of formal power series \( k[[x]] \). For an
ideal \( I \subseteq k[x] \) we will denote by \( V(I) \) the scheme defined by \( I \).

Let \( X \) be a Noetherian scheme and \( Y \) a closed subscheme of \( X \) given by a sheaf
of ideals \( I \). The formal neighbourhood \( (\hat{X}, \mathcal{O}_{\hat{X}}) \) of \( X \) in \( Y \) is the ringed space
defined by the topological space \( Y \) and the sheaf of rings \( \mathcal{O}_{\hat{X}} = \lim_{\leftarrow n} \mathcal{O}_X / I^n \)
(see [Har77], II.9). If \( X = \text{Spec} \ A \) is affine and \( p \in X \) is a closed point, then
the formal neighbourhood of \( X \) in \( p \) is the one point space \( \{p\} \) together with
the sheaf of rings given by \( \hat{A}_p \), the completion of the local ring \( A_p \) w.r.t. its
maximal ideal.

Example 24. Let \( X = \text{Spec} k[x, y]/(y^2 - x^2 - x^3) \) and \( p = 0 \). The structure
sheaf of the formal neighbourhood of \( X \) in 0 is given by

\[
\mathcal{O}_{\hat{X}} = \lim_{\leftarrow n} \mathcal{O}_X / I^n
\]

which is not an integral domain. Indeed, \( y^2 - x^2 - x^3 \) factors in \( k[[x, y]] \) as

\[
y^2 - x^2 - x^3 = (y + x \sqrt{1 + x})(y - x \sqrt{1 + x}).
\]

Therefore the formal neighbourhood of \( X \) in 0 is reducible.

Let \( X \) and \( Y \) be varieties over \( k \). For a point \( p \in X \) we denote by \( C_p(X) \) the
tangent cone of \( X \) at \( p \). It is given by the associated graded algebra of the local
ring of \( X \) at \( p \):

\[
\text{gr}(\mathcal{O}_{X,p}) = \bigoplus_{i=0}^{\infty} \mathfrak{m}_p^i / \mathfrak{m}_p^{i+1},
\]

where \( \mathfrak{m}_p^0 = \mathcal{O}_{X,p} \).
More explicit, we may define $C_0(X)$ for an affine variety $X \subseteq \mathbb{A}^n$ given by an ideal $I \subseteq k[x_1, \ldots, x_n]$ as follows: Denote by $I_*$ the ideal of initial forms of elements of $I$, where the initial form of an element $f \in k[x]$ is its homogenous part of lowest degree. Then $C_0(X) \cong k[x]/I_*$. 

For a point $x$ of a variety (or scheme) $X$ we denote by $\kappa(x)$ its residue field, i.e., $\kappa(x) = O_{X,x}/m_x$. Let $\varphi : X \to Y$ be a morphism of varieties such that the induced map $\varphi_p : \kappa(\varphi(p)) \to \kappa(p)$ is an isomorphism. We call $\varphi$ étale at $p \in X$ if the induced map on the tangent cones $d_\varphi \varphi : C_p(X) \to C_{\varphi(p)}(Y)$ is an isomorphism. If $p \in X$ is a regular closed point then the tangent cone agrees with the tangent space, and an étale morphism is a morphism whose tangent map is an isomorphism. Especially, if $\varphi$ is étale we know that $p \in X_{\text{reg}}$ if and only if $\varphi(p) \in Y_{\text{reg}}$.

**Example 25.** Let $X = \text{Spec } k[x, y]/(x - y^2)$ and $Y = \text{Spec } k[x]$ with $\varphi : X \to Y$ induced by the inclusion $k[x] \hookrightarrow k[x, y]$. Clearly for any $p = (p_x, p_y) \in X \setminus \{0\}$ the map $d_\varphi \varphi$ gives an isomorphism between $C_{p_x}(Y)$ and $C_p(X)$, thus defines an étale map. Note that this is not the case for the point $p = 0$. Note further that in the case of $k = \mathbb{C}$ we may consider $X$ and $Y$ as manifolds over $\mathbb{C}$. Then the implicit function theorem is applicable, and states that $X$ can (Euclidean-) locally at $p \in X \setminus \{0\}$ be parametrized by a neighbourhood of $p_x \in Y$.

For arbitrary schemes $X$ and $Y$ a morphism $\varphi : X \to Y$ is called étale if it is flat and unramified. It is called étale at $p$ if the induced morphism of local schemes $\varphi : X_p \to Y_{\varphi(p)}$ is étale. For the convenience of the reader we summarize some properties of étale (resp. flat and unramified) morphisms in the next Proposition. Details, especially proofs, can be found for example in the excellent sources [Har77], [KPR75] or [Mil80].

**Proposition 39.** Let $X, Y$ be schemes. For a point $x \in X$ we denote by $\kappa(x)$ its residue field, i.e., $\kappa(x) = O_{X,x}/m_x$.

1. A flat morphism of finite type between Noetherian schemes is open.
2. If $f : X \to Y$ is locally of finite type, then $f$ is unramified if and only if the sheaf of relative differentials vanishes, i.e., $\Omega^1_{X/Y} = 0$.
3. Open immersions, compositions of étale morphisms and any base changes of étale morphisms are étale.
4. Let $f : X \to Y$ be of finite type, $Y$ locally Noetherian, $x \in X$ and $y = f(x)$ so that $\kappa(x) = \kappa(y)$. Moreover, let $\theta : O_{Y,y} \to \hat{O}_{X,x}$ be the canonical morphism. Then $f$ is étale (in some neighbourhood of $x$) if and only if $\theta$ is an isomorphism.

The last observation especially implies that $\dim X = \dim Y$. Étale morphisms of varieties over $\mathbb{C}$ are morphisms which are local isomorphisms in the analytic sense, see example 25. Locally all étale morphisms are of the form

$$F : \text{Spec } R[T_1, \ldots, T_n]/(f_1, \ldots, f_n) \to \text{Spec } R$$

with $\det \frac{\partial F}{\partial T}$ a unit in $R[T]/(f_1, \ldots, f_n)$ for some ring $R$. This is equivalent to $F$ being flat and unramified (see [Mil80], Cor. 3.16, and [Mum99], III §5).
Chapter 4. Constructions with Étale Neighbourhoods

An étale neighbourhood of a point \( x \in X \) is a pair \((U, u)\) consisting of a scheme \( U \) and a point \( u \in U \) with an étale morphism \( \varphi : U \to X \) such that \( \varphi(u) = x \).

Example 26. Let \( X \) be the node in the plane with coordinate ring

\[
A = k[x, y]/(y^2 - x^2 - x^3).
\]

Clearly \( X \) is irreducible and so is \( \operatorname{Spec} A_{(x, y)} \). In the formal neighbourhood of the origin the germ of \( X \) is reducible (see example 24), since

\[
y^2 - x^2 - x^3 = (y + x\sqrt{1 + x})(y - x\sqrt{1 + x}).
\]

In the case of \( k = \mathbb{C} \) this factorization holds in an Euclidean neighbourhood of the origin, since the factors are algebraic power series, thus convergent (see [Rui93], p. 106). Though we cannot obtain this decomposition in a Zariski-open neighbourhood of 0, it will be possible in an étale neighbourhood. Consider

\[
U = \operatorname{Spec} A_a[T]/(T^2 - a)
\]

where \( a = 1 + x \) and the canonical map \( \varphi : U \to X \) induced by

\[
A_a \to A_a[T]/(T^2 - a).
\]

Let us denote the coordinate ring of \( U \) by \( B \), and set \( f = T^2 - a \). By the remark above \( \varphi \) is étale if and only if \( \partial f / \partial T = 2T \) is a unit in \( B \). But \( 2a \) is a unit in \( B \), hence \( 2T(2a)^{-1}T = 1 \). Thus \( \varphi \) is étale. On \( U \) the polynomial \( y^2 - x^2 - x^3 \) factors into \( y - Tx \) and \( y + Tx \). Therefore \( U \) is an étale neighbourhood which is reducible with two smooth branches intersecting transversally.

The connected étale neighbourhoods of \( x \in X \) form a filtered system. The local ring \( \mathcal{O}_{X,x} \) of \( X \) at \( x \) w.r.t. the étale topology is defined as

\[
\mathcal{O}_{X,x} = \lim_{(U, u) \to (x)} \Gamma(U, \mathcal{O}_U),
\]

where the limit is taken over the system of connected étale neighbourhoods \( (U, u) \) of \( x \). Let \((A, \mathfrak{m})\) be a local ring. It is called Henselian w.r.t. \( \mathfrak{m} \) if it has the following property: If \( F \in A[T] \) with \( F(0) \in \mathfrak{m} \) and \( F'(0) \in (A/\mathfrak{m})^\times \), then there exists an \( a \in \mathfrak{m} \) with \( F(a) = 0 \). As usual, \( F' \) denotes the derivative of \( F \) w.r.t. \( T \). The Henselization \( A^h \) of \( A \) is defined to be the smallest Henselian ring containing \( A \). More precisely this means: The ring \( A^h \) is Henselian, there is a local homomorphism \( i : A \to A^h \), and any other local homomorphism \( \theta : A \to B \), with \( B \) Henselian, factors through \( i \). Important examples of Henselian rings are complete local rings. Especially \( k[[x]] \), the completion of \( k[x] \) w.r.t. \( (x) \), is Henselian. But it is not the smallest Henselian ring containing \( k[x]_{(x)} \). In fact, \( k[x]_{(x)}^h \) equals \( k(x) \) the ring of algebraic power series, see [Art71]. Recall that a power series \( f \in k[[x]] \) is called algebraic if there exists a non-zero polynomial \( P(x, t) \in k[x, t] \) with \( P(x, f) = 0 \). The local ring of a scheme \( X \) at \( x \) w.r.t. the étale topology is the Henselization (w.r.t. \( \mathfrak{m}_x \)) of the local ring w.r.t. the Zariski-topology:

\[
\mathcal{O}_{X,x} = \mathcal{O}_{X,x}^A.
\]

For further details, including proofs, see [Mil80].
Remark. Note that the étale neighbourhoods are not the open sets of a topology, buttake their part in a Grothendieck topology (see for example [FGI+05, I.2]). Although it is not a “true” topology on $X$ it is still enough to allow analogous constructions (like cohomology theories).

Properties of formal and étale neighbourhoods are strongly related via the powerful Artin Approximation Theorem, see Thm. 1.10 in [Art69]:

**Theorem 17** (Artin Approximation Theorem). Let $k$ be a field or an excellent discrete valuation ring, and let $A^h$ be the Henselization of a $k$-algebra of finite type at a prime ideal. Let $I$ be a proper ideal of $A^h$. Given an arbitrary system of polynomial equations in $Y = (Y_1, \ldots, Y_N)$,

$$f(Y) = 0,$$

with coefficients in $A^h$, a solution $\bar{y} = (\bar{y}_1, \ldots, \bar{y}_N)$ in the $I$-adic completion $\hat{A}^h$ of $A$, and an integer $c$, there exists a solution $y = (y_1, \ldots, y_N) \in A^h$ with

$$y_i = \bar{y}_i \mod m^c.$$

### 4.2 Global Constructions

Let $X$ be a finite union of algebraic varieties over $k$ (i.e., integral separated schemes of finite type over $k$). All properties which will be studied here are local, hence we may assume that all varieties are affine. In fact, we will consider mainly subvarieties of some $A^n_k$, $n \in \mathbb{N}$. We say that $X$ is algebraic normal crossings (in short anc) at a point $p \in X$ if there are local coordinates $y_1, \ldots, y_n$ at $p$ such that $X$ is locally at $p$ given by $y_1 \cdots y_e = 0$ with $e \leq n$ (in the literature this property is also referred to as simple or strict normal crossings, e.g. [Kol]). By “local coordinates” we mean a regular system of parameters for the local ring $\mathcal{O}_{X^n_k,p}$. We say that $X$ is normal crossings (in short nc) at $p$ if $p$ is an algebraic normal crossings point for $X_p$, i.e., if the formal germ of $X$ at $p$ is defined by $y_1 \cdots y_e = 0$, $e \leq n$, where $y_1, \ldots, y_n$ is a formal coordinate system at $p$. A formal coordinate system is a regular system of parameters for $\mathcal{O}_{X^n_k,p}$. The locus of points in which $X$ is algebraic normal crossings (resp. normal crossings) is called the algebraic normal crossings locus of $X$ (resp. normal crossings locus of $X$) and will be denoted by $X_{nc}$ (resp. $X_{nc}$).

**Example 27.** The hypersurface $X = \text{Spec } k[x,y,z]/(x^2 - y^2 z^2) \subseteq A^3$ is algebraic normal crossings, thus also normal crossings, at all points except the origin. The origin is not a normal crossings point. In contrast, the hypersurface $Y = \text{Spec } k[x,y,z]/(x^2 - y^2 z)$ is irreducible, thus has no algebraic normal crossings points. Its normal crossings locus is $Y_{nc} = Y \setminus \{0\}$ (see Figure 4.1), which is open in $Y$.

Let $f \in \mathcal{O}_{X^n_k,p}$ be vanishing at $p \in A^n$, i.e., $f \in m_p$ (where we write $m_p$ for the maximal ideal of $\mathcal{O}_{X^n_k,p}$). Denote the differential of $f$ at $p$, i.e., the class $\frac{df}{f}(p)$ of $f$ at $p$.

**Lemma 40.** Let $X$ be a union of hypersurfaces $X_i = \text{Spec } k[x]/(f_i)$, $1 \leq i \leq s$, $s \in \mathbb{N}$. Then $X$ is anc at $p \in A^n$ if and only if $p \not\in (X_i)_{\text{sing}}$, for all $i$ and the \{df_i(p); f_i(p) = 0\} are k-linearly independent.
Proof. The “if” part is obvious. For the other direction let $X$ and $p$ fulfill the conditions above. Since the $df_i(p)$ are $k$-linearly independent, the $f_i$ vanishing at $p$ are part of a regular system of parameters of $\mathcal{O}_{\mathbb{A}^n, p}$ (see [Mat89], Thm. 14.2) from which the assertion follows immediately (see also [Bod04]). □

Proposition 41. The algebraic normal crossings locus of a finite union of hypersurfaces is open.

Proof. Let $X = \bigcup_{1 \leq i \leq s} X_i$ where $X_i$ is the hypersurface defined by $f_i \in k[x]$. If $p$ lies in the intersection $X_i \cap X_j$ of two hypersurfaces and is not an anc point of $X_i \cup X_j$, then $p \in X_i \cap X_j \cap X_l$ is not an anc point of $X_i \cup X_j \cup X_l$ for any $l$. Define the following (Zariski-) closed subsets of $X$. For $q \geq 1$:

$$K_q = \bigcup_{(i_1, \ldots, i_q)} (X_{i_1} \cap \cdots \cap X_{i_q} \cap V(M_q(df_{i_1}, \ldots, df_{i_q}))),$$

where $M_q(df_{i_1}, \ldots, df_{i_q})$ denotes the ideal generated by all $q$-minors of the matrix $(df_{i_1}, \ldots, df_{i_q})$ and the union is taken over all $q$-tuples $(i_1, \ldots, i_q)$ with distinct entries $i_j \in \{1, \ldots, s\}$. Finally, set $K = \bigcup_{q=1}^s K_q$. Clearly $K$ is closed and contains by Lemma 10 all non-anc points. Conversely, no point of $K$ is an anc point. Thus $X_{\text{anc}} = X \setminus K$ is open. □

Example 28. Figure 4.2 illustrates Proposition 41. Here $X$ is the union of three plane curves.

Figure 4.2: The points $a$ and $c$ are not anc, but $b$ and $d$ are.

Figure 4.1: $X = V(x^2 - y^2z^2)$ and $Y = V(x^2 - y^2z)$. 
4.3 Applications

In this section we give some applications of étale neighbourhoods. The prototype of questions we study will be the following: Let $X$ be a variety, $p \in X$ a closed point. Moreover, let $\mathcal{P}$ be a property of the formal neighbourhood $\hat{O}_{X,p}$, e.g., normal crossings, reducible, ... . Is the set of points $q \in X$ for which $\hat{O}_{X,q}$ has property $\mathcal{P}$ open (resp. closed or locally closed) in the Zariski-topology?

4.3.1 Normal Crossings Locus

As a first example we study the property of being normal crossings, see 4.2 and Theorem 18 below.

Theorem 18. The normal crossings locus $X_{nc}$ of a hypersurface $X \subseteq \mathbb{A}^n$ is open in $X$.

Proof. (i) We first show that if $X = \text{Spec } k[x]/(f)$ is normal crossings at $p$, then there exists an étale neighbourhood $\varphi: (U, u) \to \mathbb{A}^n$ of $p$ such that $u$ is an algebraic normal crossings point of $\varphi^{-1}(X)$. Without loss of generality we may assume $p = 0$. Since $p \in X_{nc}$ there exist $\bar{g}_1, \ldots, \bar{g}_m \in k[[x]]$, $m \leq n$, building part of a regular system of parameters of $\hat{O}_{\mathbb{A}^n,0}$ such that $f = \bar{g}_1 \cdots \bar{g}_m$.

By Theorem 17 there exists an étale neighbourhood $\varphi: (U, u) \to \mathbb{A}^n$ with $\varphi(u) = p$, $\varphi^*(f) = g_1 \cdots g_m$, on $U$ and $g_i = \bar{g}_i \mod (x)^c$. Note that $g_1, \ldots, g_m$ are regular on $U$. By choosing the constant $c$ of Theorem 17 equal to 2 we can assure that the $g_i$ are part of a regular system of parameters of $\mathcal{O}_{U,u}$. Thus $\varphi^{-1}(X)$ is algebraic normal crossings at $u$.

(ii) If $w \in U$ is an algebraic normal crossings or normal crossings point, then $\varphi(w)$ is a normal crossings point of $X$. This follows immediately from Proposition 39 (4).

(iii) By (i) every point $p \in X_{nc}$ has an étale neighbourhood

$$\varphi_p: (U_p, u_p) \to X$$

so that $\varphi_p^{-1}(X)$ is anc at $u_p$. By Proposition 41 we see that $(U_p)_{anc} \subseteq U_p$ is open. Openness of étale maps (see Proposition 39 (1)) implies that $\varphi_p((U_p)_{anc}) \subseteq X$ is open, and so is

$$\bigcup_{x \in X} \varphi_p((U_x)_{anc}) \subseteq X.$$

$\square$

Let $X = \text{Spec } k[x]/(f)$ be a scheme defined by a not necessarily reduced polynomial $f \in k[x]$. Analogous to the normal crossings locus of $X$ we ask for the monomial locus $X_{mon}$ of $X$. This is the locus of points $p \in X$ so that there exist formal coordinates $y_1, \ldots, y_n$ with $f = y^\alpha$ for some element $\alpha \in \mathbb{N}^n$. Denote by
$X_{\text{red}}$ the reduced scheme associated to $X$. Then $X_{\text{mon}} = (X_{\text{red}})_{\text{nc}}$. Indeed, let $f_1, \ldots, f_s$ be the distinct irreducible factors of $f$ in $\mathcal{O}_{A^n, p}$ defining hypersurfaces $X_i$. By definition $\mathcal{O}_{X_{\text{red}}, p}$ is reduced. Since it is essentially of finite type (see [Mat89], p. 232, 260), we conclude that $\hat{\mathcal{O}}_{X_{\text{red}}, p}$ is reduced. The same is true for $\hat{\mathcal{O}}_{X_i, p}$. If $p \in X_{\text{mon}}$ then each irreducible component of $f_i \in \hat{\mathcal{O}}_{A^n, p}$ corresponds to one of the $y_1, \ldots, y_n$ after a change of coordinates. Therefore:

$$p \in X_{\text{mon}} \Leftrightarrow p \in \cap_i (X_i)_{\text{nc}} \Leftrightarrow p \in (X_{\text{red}})_{\text{nc}}.$$ 

The last theorem thus implies:

**Corollary 42.** Let $X = \text{Spec } k[x]/(f)$ be a hypersurface in $\mathbb{A}^n$ defined by a not necessarily reduced polynomial $f \in k[x]$. Then the monomial locus $X_{\text{mon}}$ of $X$ is open in $X$.

### 4.3.2 Mikado Schemes

Let $X$ be an excellent scheme. Denote by $X_p^1, \ldots, X_p^N$, $N = N(p) \in \mathbb{N}$ the components of $X$ passing through $p$. Then $X$ is said to be mikado at $p$ if $p \in (X_p^i)_{\text{reg}}$ for all $1 \leq i \leq N$ and $p \in (Z_p)_{\text{reg}}$, where $Z_p = X_p^1 \cap \cdots \cap X_p^N$. The locus of all mikado points of $X$ will be denoted by $X_{\text{mik}}$.

**Example 29.** Let $X = \text{Spec } k[x, y]/(y(y-x^2))$ and $Y = \text{Spec } k[x, y]/(xy(y-x^2))$. Clearly, $X$ is not mikado at 0, but $Y$ is; neither of them is normal crossings at the origin.

In order to successfully apply the étale construction to consider the locus of “formally mikado points” in an irreducible scheme it will be necessary that $X_{\text{mik}}$ is open in $X$. The next example gives a counterexample: $X \setminus X_{\text{mik}}$ is locally closed but not open. In this way we can construct examples of schemes/varieties which have only constructible $X_{\text{mik}}$, which is – in the algebraic category – the worst possible behaviour.

**Example 30.** Consider $X = \text{Spec } k[x, y, z]/(yz(x-z)(y-x^2))$, which is a union of four hypersurfaces in $\mathbb{A}^3$. It’s easy to see that $X \setminus X_{\text{mik}} = V(x, y) \setminus V(x, y, z)$, which is locally closed in $X$ but not open, see figure 4.3.

Figure 4.3: The set $X \setminus X_{\text{mik}}$ is locally closed but not open.
4.3 APPLICATIONS

4.3.3 Formally Irreducible

Let \( X = \bigcup_{1 \leq i \leq s} X_i \) be a union of algebraic varieties (not necessarily hypersurfaces). We say that \( X \) is irreducible (resp. formally irreducible) at \( p \in X \) if \( O_{X,p} \) (resp. \( \hat{O}_{X,p} \)) is an integral domain. Otherwise \( X \) is called reducible (resp. formally reducible) at \( p \). We denote the locus of irreducible resp. formally irreducible \( p \in X \) by \( X_{\text{ire}} \) resp. \( X_{\text{fire}} \). Analogously we denote by \( X_{\text{re}} \) the complement of \( X_{\text{ire}} \) in \( X \).

It is natural to try to prove an analogous result for \( X_{\text{fire}} \) as for \( X_{\text{nc}} \) with the same method of proof. Let \( X \) be a finite union of algebraic varieties \( X_1, \ldots, X_s \). Then \( X_{\text{nc}} \subseteq X \) is closed. This follows from the simple fact that

\[
X_{\text{re}} = \bigcup_{i \neq j} (X_i \cap X_j).
\]

Thus \( X_{\text{ire}} \) is open. Note that \( X_{\text{ire}} \) will in general contain points where one of the \( X_i \) is formally reducible. This causes troubles in step (iii) of the proof of Theorem 18. Indeed, using the notation there, the sets \( \varphi_x((U_x)_{\text{ire}}) \) are useless for our purpose (since they might contain formally reducible points).
Bibliography

Appendix
Acknowledgements

The research presented in this thesis has been carried out at the Departments of Mathematics at the University of Innsbruck (2005-2007) and the University of Vienna (2007-2009). Financial support was provided by the FWF-Project P18992 “Solving Algebraic Equations” and the “Doktoratsstipendium der LFU Innsbruck” (in 2006); travel fundings have been available through the ÖAD (“Acciones Integradas”, “WTZ Ungarn”, “Amadée”). I appreciate these institutions for their support.

The author acknowledges his debt to those who have helped along the way and influenced his understanding of the mathematics behind.

In particular, I wish to express my gratitude to my advisor, Herwig Hauser. Not only did he offer a stimulating working environment and permanent encouragement, but also changed my view on mathematics, especially the balance of Bourbakism and artistic freedom, drastically.

Furthermore let me thank Bernhard Lamel, Luis Narvaez Macarro and Josef Schicho for their willingness to serve as possible referees for the present PhD thesis.

Special thanks go to Josef Schicho, co-project leader of the FWF project P18992, for many valuable scientific discussions and his invitation to research stays at the RICAM Linz. From him and his research group I learned a lot about the algorithmic aspects of algebraic geometry and mathematics in general. In particular I would like to mention Tobias Beck and Georg Regensburger. Both offered invaluable advice concerning math and its adverse effects.

I am deeply grateful to Ana Bravo, Antonio Campillo, Santiago Encinas, Shihoko Ishii, Bernhard Lamel, Monique Lejeune-Jalabert, the organizers of YMIS and Orlando Villamayor for their hospitality respectively scientific and financial support during various stages of my PhD studies.

Many colleagues and friends made life easier and definitely more fun over the past years. Thanks for the support: Sebastian B., Eleonore F., Martin F., Alexandra F., Anne-Katrin H., Niels L., Brian M., Andreas N., Martin S., David S., Johannes T., Dennis W. and Dominik Z. Especially I am indebted to Sebastian Gann for taking the part of the crisis line in many, many occasions.

Last but not least, I’m deeply grateful to my family for their constant support; thanks Thomas for the permanent advice of an elder brother! Finally, I have to mention my companion Dominique Wagner; I owe her much. Besides many interesting scientific discussion she was a permanent source of encouragement and support during hard times!
Abstract English

The main objective of this PhD thesis is the study of the linearization principle in algebraic and local analytic geometry.

The Rank Theorem for analytic maps between convergent power series spaces developed by Hauser and Müller is extended to a purely algebraic setting: A Rank Theorem for a new class of maps on power series spaces (over a field of characteristic zero), so-called textile maps, is proven. This class includes the classic case of substitutions of power series. Moreover, we consider a Rank Theorem with parameters and give a corresponding result for power series with coefficients in a test-ring (basically a local ring with nilpotent maximal ideal).

The developed theory is used to show that several important results from singularity theory are consequences or special instances of the linearization principle, i.e., the corresponding Rank Theorem. These include a trivialization theorem by Denef-Loeser, the Grinberg-Kazhdan-Drinfeld formal arc theorem, an inversion theorem by Lamel-Mir, Tougeron’s implicit function theorem as well as the approximation theorems by Artin and Wavrik.

In the second part of the thesis approaches and ideas for the study of zero sets of textile maps, so-called felts, especially in the case of arc spaces, are given. This leads to the study of quotients of polynomial rings in countably many indeterminates.

Finally, some constructions using étale neighbourhoods are used to proof that the normal crossings locus of a variety over an algebraically closed field of arbitrary characteristic is open. The same question is treated for other geometric properties which have applications in resolution of singularities.
Abstract Deutsch

Die vorliegende Dissertation beschäftigt sich mit dem Linearisierungsprinzip in der algebraischen und lokal analytischen Geometrie.

Im zweiten Teil der Arbeit werden Ansätze und Ideen zum Studium der Nullstellmengen von textilen Abbildungen, sogenannten Filzen, erörtert. Dies führt zu Untersuchungen von Polynomringen in abzählbar vielen Variablen und deren Quotienten. Wichtigstes Beispiel stellen hier die Arc Spaces dar.

Das letzte Kapitel beschäftigt sich mit der Menge aller Punkte einer Varietät, in denen sie normale Kreuzung ist. Durch Konstruktionen mit étalen Umgebungen wird gezeigt, dass diese Menge offen ist. Die gleiche Frage wird für andere geometrische Problemstellungen behandelt, die zum Teil Anwendungen in der Auflösung von Singularitäten haben.

Curriculum Vitae

Research Interests

Algebraic and Analytic Geometry, Interrelations with Commutative Algebra and Complex Analysis, especially CR-Geometry.

Personal Information

Date of Birth       May 7, 1981
Place of Birth     Salzburg, Austria
Nationality        Austria
Marital Status     Single

Education

2008 – Present     PhD Student in Pure Mathematics, University of Vienna, Department of Mathematics, Vienna, Austria.
2005 – 2008        PhD Student in Pure Mathematics, University of Innsbruck, Department of Mathematics, Innsbruck, Austria.
2000 – 2005        MS in Technical Mathematics, University of Innsbruck, Department of Mathematics, Innsbruck, Austria.
                   Graduated with high honours.
1999 – 2000        Military Service
1991 – 1999        High school education at the BRG Akademiestrasse Salzburg.
                   Matura with excellence in June 2000.
1987 – 1991        Elementary school in Salzburg

Employment History

2006 – Present     Research Assistant, FWF-project P18992, Innsbruck and Vienna.
**Scientific Activities**

2009  
Participant in the conference FPSAC09 in Hagenberg, *Austria*  
Research stay at the University of Versailles, *France*

2008  
Research stay at the Tokyo University of Technology, *Japan*; Talk (at Nihon University, Tokyo): “Linearization Problems in Geometry”.  
Participation in the conference “On the resolution of singularities” in Kyoto, *Japan*.  
Participation in the conference “Deformations of Surfaces” at the Alfréd Rényi Institute of Mathematics, Budapest, *Hungary*.  
Research stay at RISC Linz, *Austria*; Talk: “Basic Properties of Jet and Arc Algebras”.  
Coorganizer of the “Vienna Algebra Day” in Vienna, *Austria*.  
Coorganizer of the “Vienna Geometry Day” in Vienna, *Austria*.  
Participant in the “YMIS winter school – Arc spaces, Integration and Combinatorial Algebra” in Sedano, *Spain*.

2007  
Organizer of the “First $\omega$–Conference in Algebraic Geometry” in Obergurgl, *Austria*.  
Participant in the workshop “Algebraic Geometry” in Nové Hrady, *Czech Republic*; Talk: “Primary Decomposition of ideals of Jet Spaces”.  
Participant in the conference “Singularities, Computing and Visualization” in Segovia, *Spain*.  
Participant in the “YMIS winter school – Algebra and Topology of Singularities” in Sedano, *Spain*.  

2006  
Organizer of the workshop “Singularities” in Obergurgl, *Austria*.  
Participant in the “International Congress of Mathematicians” in Madrid, *Spain*.  
Participant in the summer school “Resolution of singularities” in Trieste, *Italy*.  
Research stay in Madrid, *Spain*.  
Participant in the “YMIS winter school – Combinatorial Convexity and Algebraic Geometry. Applications” in Sedano, *Spain*.  
Research stay in Valladolid, *Spain*.

2005  
Participant at the winter school “Singularities” in Marseille, *France*. 

---

Fall 06/07  
**Teaching Assistant**, University of Innsbruck, Excs. in “Math. for Physicists 1”.

Fall 05/06  
**Teaching Assistant**, University of Innsbruck, Excs. in “Algebra”.

Oct. ’04 – Dec ’05  
**Research grant** (“Forschungsbeihilfe”) in the framework of the FWF project “Resolution of Singularities”, *University of Innsbruck*. 

---

102
Academic Honors and Awards

2006 – 2007  Research fellowship for writing my Ph.D. Thesis ("Doktoratsstipendium") from the University of Innsbruck.
2006 and 2007 Scholarship for writing scientific papers ("Förderungsstipendium") from the University of Innsbruck in the years 2006 and 2007.
2005 Prize Winner at the Week for Industrial Modelling in Innsbruck; Topic: Bindemitteloptimierung.
